This guide is intended to be used by the Disposal Group Supervisor or designee on a USDA APHIS Incident Management Team during an animal health emergency response.

Contact the National Incident Coordination Group Disposal Technical Specialist for additional guidance (see current Incident Action Plan).
The compilation of the Disposal Guidebook was a collaborative effort. Many individuals contributed their time and talents to this project. We wish to thank the following people who made this manual possible:

This guidebook was compiled by Texas A&M University, College of Veterinary Medicine & Biomedical Sciences through a cooperative agreement with the United States Department of Agriculture, under Agreement No. 15-9100-1492-CA.
Based on the facility, location, housing, and other factors, carcasses are managed using one or more methods: composting, burial, incineration, rendering, or landfilling. Get state environmental agency written approval of selected option(s).

Animal appraisal process is initiated; prior to depopulation, every attempt should be made to collect inventory and other data for indemnity so that fair market value can be paid for the animals.

Premises suspected of having foreign animal disease maybe placed under standstill notice or hold order by the State. Samples are submitted to NVSL and State NAHLN lab.

Within 24-hours of a presumptive positive (case definition), animals will be depopulated to limit the spread of the virus and further environmental contamination.

Virus must be eliminated from barn, equipment, and all affected areas of the farm. Methods will be site-specific based on Incident Command guidance and preference of producers.

Required environmental samples are collected and tested to confirm that the virus is gone before further steps are taken to reestablish production.

At all times, and especially after restocking, the owner maintains the highest biosecurity standards to protect their animals. For biosecurity tips, go to www.aphis.usda.gov/fadprep.

USDA and State officials must approve restocking; after approval, producers can restock their facilities from an disease negative source and resume production.

Note: NAHLN = National Animal Health Laboratory Network; NVSL = National Veterinary Services Laboratories.

RESPONSE PROCESS

SECTION 1

OPERATIONS PROCEDURES

Ensure state environmental agency has approved disposal method in writing (see list of state contacts available at go.usdatraining.com/agencies).

OPERATIONAL TIMELINE FOR DISPOSAL

- Perform disposal as approved by the state environmental agency, ensuring all regulations are followed.
- Promptly discuss significant impacts to the schedule with the Operations Chief.
- Ensure the rate of depopulation does not exceed the rate of storage and disposal to avoid attracting vectors.

QUALITY ASSURANCE/QUALITY CONTROL

SITE/CASE MANAGER

- Step 1: Monitor disposal operations at the frequency specified by the Disposal Group Supervisor.

DISPOSAL GROUP SUPERVISOR

- Step 2: Verify that all activities are in accordance with the Site Specific Disposal Plan and all applicable regulatory approval or permit conditions.
- Step 3: Take immediate action to rectify significant deviations from the approved plan or state/federal environmental regulations.
- Step 4: Gain approval to change the plan if the deviations are needed to accommodate field conditions from Operations Chief or state environmental officials.

DEMOBILIZATION

- Remove miscellaneous debris, equipment, excess materials, disposal byproducts, and other waste in accordance with the Site Specific Disposal Plan.
- Leave the facility in broom-clean condition in preparation for subsequent activities.

|---------------------------------| |
| Acres available for burial:     | |

# Definitions

<p>| <strong>Biomass</strong> | The total quantity or weight of livestock/poultry carcasses and associated biodegradable material requiring management. |
| <strong>Capacity</strong> | Equal to throughput times availability where throughput is the amount of biomass that can be processed per day per system and availability is the number of systems available. |
| <strong>Composting</strong> | A natural biological decomposition process that takes place in the presence of oxygen (air). Composting process control parameters include the initial ratios of carbon and nitrogen rich materials, the amount of bulking agent added to assure air porosity, the pile size, moisture content, and turning frequency. |
| <strong>Depopulation</strong> | (also known as culling, destruction, and/or euthanasia) is a method by which large numbers of diseased and/or suffering animals are killed quickly and efficiently with as much consideration given to the welfare of the animals as practicable. It may be practiced during an animal health emergency, such as a major disease outbreak to eliminate animal suffering or help prevent or mitigate the spread of the disease through the elimination of infected, exposed, or potentially exposed animals. It also serves to remove contaminated livestock from the food supply, protect the nation’s agricultural and national economy, and safeguard public health. Animals should not be depopulated until a disposal plan is in place. |
| <strong>Grinding</strong> | An operation that reduces biomass particle size. Grinding implies that particles are broken apart largely by smashing and crushing rather than tearing or slicing. |
| <strong>Groundwater</strong> | Water below the land surface in a zone of saturation. |
| <strong>Leachate</strong> | Any liquid material that drains from land, waste, or stockpiled material and contains significantly elevated concentrations of contamination derived from the material that it has passed through. |
| <strong>Off-site</strong> | Include (a) small on-farm incinerators, (b) small and large incineration facilities, (c) crematoria, and (d) power plant incinerators. Unlike open-air burning and air-curtain incineration, fixed-facility incineration is wholly contained and, usually, highly controlled. |
| <strong>Fixed-facility incinerators</strong> | |
| <strong>On-site Burial</strong> | In the context of this document refers to excavating a trench or pit into the earth, placing carcasses in the trench, and covering with the excavated material (backfill). |
| <strong>Open-air burning</strong> | Includes burning carcasses (a) in open fields, (b) on combustible heaps called pyres, and (c) with other burning techniques that are unassisted by incineration equipment. |
| <strong>Pathogens</strong> | Any organism capable of producing disease or infection |
| <strong>Permitted Landfills</strong> | Modern Subtitle D landfills that are highly regulated operations, engineered and built with technically complex systems specifically designed to protect the environment and include liners and leachate controls. These landfills are distinguished from older landfills in the U.S. (sometimes called small arid landfills) which were constructed before Subtitle D regulations were effective, and therefore were not constructed with sophisticated containment systems. |
| <strong>Premises</strong> | Geographically and epidemiologically defined locations, including a ranch, farm, stable, or other establishment. |</p>

**Total Points** | 71 | 69 | 66 | 62 | 53 | 48  
**Average Score** | 4.7 | 4.6 | 4.4 | 4.1 | 3.5 | 3.2

### Color Key and Matrix Explanation

- **Ideal** (Green) technologies were scored 3 points
- **Not Ideal** (Yellow) technologies were scored 2 points
- **Not Suitable** (Red) technologies were scored 1 point

Scores were weighted according to the importance of the criteria. Scores for each column were totaled then averaged to obtain the ranking.

Developed by USDA APHIS in collaboration with the DHS S&T Depopulation, Disposal, and Decontamination (3D) Program and federal interagency 3D Integrated Product Team (IPT)
Matrix Footnotes

Mobile, new, or innovative technologies are not included in this matrix, but a separate table for such technologies is under development.

Values in matrix may be incident specific.

1. Public health risk – based on the UK 2001 human health qualitative risk assessment which excluded composting and mobile technologies. The rankings are consistent with the public health risks tabulated by the United Kingdom (UK) Department of Health (now the Department for Environment, Food and Rural Affairs), in “A Rapid Qualitative Assessment of possible risks to Public Health from current Foot & Mouth Disposal Options, Main Report,” June 2001.

2. Biosecurity – if process can be contained and easily disinfected = 3, if process is somewhat contained, but the processing area is difficult to disinfect = 2, if process is not contained = 1

3. Pathogen Inactivation – If process completely inactivates pathogen = 3, partial inactivation = 2, no inactivation = 1

4. Environmental sustainability – low risk of environmental contamination and useful end product = 3, low risk of contamination or useful end product = 2, risk of environmental contamination and no useful end product = 1

5. Transport carcasses offsite – Yes = 1, No = 3

6. Volume reduction – process reduces volume of biomass = 3, same volume = 2, increases volume = 1

7. Availability – option is widely available = 3, regional or somewhat available = 2, very limited availability = 1

8. Throughput – the amount of biomass that can be processed per day. If >200K lbs/day = 3, between 200K lbs/day - 50K lbs/day = 2, <50K lbs/day = 1. Note: Throughput X Availability = Capacity

9. Speed to implement – how quickly can option begin taking first carcasses including obtaining regulatory approval where immediately = 3, <5 days = 2, more than 5 days = 1

10. Public acceptance – likelihood of public protests where low = 3, medium = 2, and high = 1

12. Efficiency – amount of inputs (utilities, chemicals, fuel, carbon source) to contain and stabilize biomass over a short period of time

13. Operability – ease of implementation, for example simple to do, operators readily trained and available

14. Regulatory limitations – permits or regulator exemptions would have to be obtained in order to utilize this disposal method

15. Denial of use – land or equipment is no longer able to be used for its intended purpose due to disposal method
Carcass Management Decision Cycle

1. Is in-house Composting feasible?
   See checklist.

2. If not, is Outdoor Composting feasible?
   See checklist.

3. If not, is site suitable for Open Air Burning?
   See checklist.

4. If not, is Onsite Burial permitted?
   See checklist.

5. If not, are Mobile Technologies available?
   See checklist.

6. If not, are landfills available?
   See checklist.

7. If not, are rendering plants available?
   See checklist.

8. If not, are incinerators available?
   See checklist.

For more information about all options, see APHIS online training modules: go.usdatraining.com/Disposal_tree

NOTE: The order of options in the Carcass Management Decision Cycle differs from the Matrix because on-site options are preferable to disease management officials.
Carcass Management Options Checklists

First Option - Is in-house composting feasible?

- Based on the opinion of an animal mortality composting subject matter expert (SME) from the APHIS roster, are the site conditions suitable for in-house composting of the number of animals affected?
  
  - See USDA Mortality Composting Protocol for Avian Influenza Infected Flocks (also at go.usdatraining.com/HPAI)
  
  - Poultry houses have sufficient interior space to maneuver composting equipment and construct windrows (e.g., enough open space and ceiling height to allow loaders to construct windrows 6-8 feet high and 12 feet wide. Houses with columns, such as double-deck houses, restrict such formations.)
  
  - Poultry houses are located in an area that is accessible by trucks delivering carbon source and equipment removing compost
  
  - Poultry houses can be secured against vandals, scavengers, and disease vectors such as wild birds

- If the poultry houses are suitable, consider the duration of time it takes to fully compost and determine if the following issues can be overcome:
  
  - Personnel required to ensure proper construction, maintenance, and temperature monitoring of windrows.
  
  - Need for pest management.
  
  - Denial of use of poultry houses while composting (at least 30 days).

- If so, is there a sufficient local supply of carbon source such as wood chips (1-2 pounds carbon source per pound of biomass)?
  
  - Check with local agencies and organizations to determine if stockpiles of carbon source are available (e.g., parks department and landfills). Ensure that the carbon source is free of any pests or pathogens which could threaten local species. (See Carbon Sources for Windrow Construction)

- If so, have you arranged for the necessary personnel, equipment and supplies to be delivered to the site?
  
  - Mortality composting subject matter expert
  
  - Composting supplies and carbon source
  
  - Personal protective equipment
  
  - Cleaning and disinfecting (biosecurity) supplies
  
  - Hand tools
  
  - Heavy equipment (mid-size skid-steer loaders, tractors with bucket loaders)
  
  - Qualified equipment operators

- If in-house composting is an option, see In-House Composting training module at go.usdatraining.com/Disposal and implement composting. If not, continue to Second Option.
Second Option – Is outdoor composting feasible?

Identify a suitable site on premises or in a centralized location in accordance with the checklist items below.

- If off-site consider the need for secure transport

Based on approval of the state environmental agency and the composting SME from the APHIS roster, are the site conditions suitable for composting the number of animals affected?

- See USDA Mortality Composting Protocol for Avian Influenza Infected Flocks (also at go.usdatraining.com/HPAI)

- Adequate land area to build compost piles (assume (237) 1000-pound cows per acre, (1,185) 200-pound swine or sheep per acre, or (47,500) 5-pound poultry per acre).

- Required distance from water wells, surface water bodies (lakes, streams, rivers, etc.), sinkholes, seasonal seeps or other landscape features that indicate the area is hydrologically sensitive, based on guidance from state environmental officials.

- Consider all groundwater pathways including the presence of drain tiles, soil characteristics, depth to groundwater, use of groundwater etc.

- Located away from neighbors and/or out of sight.

- Located downwind from neighbors and/or houses.

- Located away from environmentally-sensitive areas.

- Located close to the livestock or poultry facility or have clear access for transport.

- Clear of overhead utility lines.

- Void of excess water.

- Located on a gentle slope (1%-3%) so there will be no water ponding.

- Consider the need for an impermeable base and/or protective cover to prevent leachate generation and migration.

If the site is suitable, consider the duration of time it takes to fully compost and determine if the following issues can be overcome:

- Personnel required to ensure proper construction, maintenance, and temperature monitoring of windrows.

- Need for pest management.

- Potential for extreme weather (e.g., hurricane) to disturb pile.

- Denial of use of land area while composting (minimum 30 days).

If so, is there a sufficient local supply of carbon source such as wood chips (1-2 pounds carbon source per pound of biomass)?

- Check with local agencies and organizations to determine if stockpiles of carbon source are available (e.g., parks department and landfills). Ensure that the carbon source is free of any pests or pathogens which could threaten local species. See Carbon Sources for Windrow Construction.
### DECISION TOOLS

**If so, have you arranged for the necessary equipment and supplies to be delivered to the site?**
- [ ] Personnel
- [ ] Composting supplies and carbon source
- [ ] Personal protective equipment
- [ ] Cleaning and disinfecting (biosecurity) supplies
- [ ] Hand tools
- [ ] Heavy equipment (mid-size skid-steer loaders, tractors with bucket loaders, trucks, containers and covers if transporting, leak-resistant material for lining carcass transport containers)

**If composting is an option see Outdoor Composting training module at go.usdatraining.com/Disposal and implement composting. If not, continue to Third Option.**

### Third Option - Is site suitable for open air burning?

**Will local and state agencies allow open burning at the site?**
- [ ] Local Fire Department
- [ ] State Department of Agriculture, Animal Health
- [ ] State Department of Environment or Natural Resources
- [ ] USDA-APHIS
- [ ] USEPA

**Will open burning release air pollutants in excess of public health standards?**

**If so, can the permit conditions, such as measures to control the spread of fire, distance to occupied buildings etc. be met?**
- [ ] What environmental testing (e.g., water, ash, soils) are required and at what frequency?
- [ ] How and where would the ash be disposed of?
- [ ] Are weather conditions (e.g., wind and drought) suitable for open air burning?

**If so, will burning be publically unacceptable?**

**If so, have you arranged for the necessary personnel, equipment and supplies to be delivered to the site?**
- [ ] Adequate source of combustible material and fuel to keep the fire going. Verify that type of fuel is acceptable to regulatory agencies.
- [ ] Other equipment including mechanical chains and lifting equipment.
- [ ] Personnel properly trained in the use of this equipment.
- [ ] Fire safety equipment also should be readily available.

**If open air burning is an option, see On-Site Treatment/Burial training module at go.usdatraining.com/aphis_tools and implement on-site open air burning. If not, continue to Fourth Option.**
Fourth Option - Is site suitable for on-site burial?

- Will state environmental agency permit burial at the site?
  - Consider soil suitability (see USDA NRCS online Web Soil Survey at go.usdatraining.com/WSS based on guidance from state environmental officials?)
  - Consider potential for leachate to contaminate groundwater
  - Consider all groundwater pathways including the presence of drain tiles, soil characteristics, depth to groundwater, use of groundwater etc.
  - Consider potential for the burial site to create a stability or explosion hazard in nearby structures from production of methane.

- If so, is adequate land available for on-site burial? (assume 1.42 acres per 1000 half-ton cows, 0.28 acres per 1000 swine or sheep, and 0.01 acres per 1000 poultry)

- If so, will land owner accept on-site burial, associated environmental liabilities, and potential loss of property value or use?

- If on-site burial is an option, see the On-Site Treatment/Burial training module at go.usdatraining.com/Disposal and implement on-site burial. If not, continue to Fifth Option.

Fifth Option - Are mobile treatment technologies available for your area?

- Contact all appropriate mobile treatment technology vendors.
  - Verify the units are available for deployment to your site.
  - Verify your ability to meet all site/utility requirements.
  - Verify units can be fully disinfected after use.
  - Verify the units have adequate capacity to meet your needs.
  - If the capacity is less than needed, can the carcasses be stored/refrigerated while awaiting disposal?
  - Verify the availability of skilled operators and spare parts to keep the units operational.
  - Verify the unit can be set-up on the site (e.g., the site has appropriate grading)

- If so, is the technology permitted by the state environmental agency?

- If so, can the permit conditions be met?

- If so, can the process byproducts be readily disposed?

- If mobile treatment is an option, see On-Site Treatment/Burial training module at go.usdatraining.com/Disposal and implement. If not, continue to Sixth Option.
### Sixth Option - Can off-site permitted landfill be used?

- **Consult with state environmental agency for landfill advice.**

- **Access a comprehensive list of landfills using the I-WASTE Tool at go.usdatraining.com/I-WASTE.**
  - Log on to the I-WASTE Tool and obtain a password if you do not currently have one.
  - Enter userid and password.
  - Choose treatment and disposal facilities button on the lower left.
  - Enter filter criteria such as “facility type (e.g., rendering, incinerators, or landfill)”
  - Note that construction debris landfills are not suitable for carcass disposal, and hazardous waste landfills are not necessary unless the carcasses are contaminated with a hazardous material causing them to be classified as hazardous
  - Enter State or EPA region, and click “View List of Facilities” button.

- **Contact facilities and determine if they will accept your livestock or poultry and meet some or all of your capacity needs.**
  - If there is insufficient capacity, consider fast-tracking expansion of existing landfill or permitting of new landfill for this purpose.
  - Consider potential environmental and biosecurity concerns.
  - Verify landfill has no outstanding permit violations
  - Procure landfill services through appropriate Incident Management Team branch.

- **If the landfill will accept the material, arrange for biosecure transport.**
  - Obtain controlled movement permit for transport of infected carcasses
  - Determine type of transport vehicles required. If the waste must travel on public roads, it should be transported in closed, leak-resistant trucks or dumpsters. Secondary containment may be needed, depending on the type of waste being transported. See Landfill Disposal Guidance
  - Work with Depopulation Group Supervisor within the Incident Command System to determine how many animals can be depopulated per day and how many trucks will be needed for transport per day, ensuring the rates are about the same. If not, arrange for covered, leak-resistant storage.
  - Pre-identify transport routes to minimize exposure to susceptible premises.

- **If permitted landfilling is an option, see the Secure Transport and Off-Site Treatment/Burial training modules at go.usdatraining.com/Disposal and implement off-site permitted landfilling. If not, continue to Seventh Option.**
Seventh Option - Is rendering available?

- Will state environmental agency approve rendering?
  - If so, see a complete list of renderers at go.usdatraining.com/NRA or the EPA database at go.usdatraining.com/I-WASTE.
    - Log on to the I-WASTE Tool and obtain a password if you do not currently have one.
    - Enter userid and password.
    - Choose treatment and disposal facilities button on the lower left.
    - Enter filter criteria such as “facility type (e.g., rendering, incinerators, or landfill)”
    - Enter State or EPA region, and click “View List of Facilities” button or map facilities.

- Contact facilities and determine if they will accept your livestock or poultry and meet some or all of your capacity needs.
  - If the capacity is less than needed, can the carcasses be stored/refrigerated while awaiting disposal?

- If so, arrange for storage and transport to rendering facility for disposal.
  - Determine if any permits are required for transport of infected carcasses.
  - Determine type of transport vehicles required. If the waste must travel on public roads, it should be transported in closed, leak-proof trucks or dumpsters. Secondary containment may be needed, depending on the type of waste being transported. Contact National Veterinary Stockpile.
  - Work with Depopulation Group Supervisor within the Incident Command System to determine how many animals can be depopulated per day and how many trucks will be needed for transport per day, ensuring the rates are about equal. If not, arrange for leak-resistant, covered storage.
  - Pre-identify transport routes to minimize exposure of susceptible premises.

- If rendering is an option, see Secure Transport and Off-Site Treatment/Burial training modules at go.usdatraining.com/Disposal and implement rendering. If not, continue to Eighth Option.

Eighth Option - Can off-site incinerator be used?

- Will state environmental agency approve incineration?
  - If so, see a complete list of incinerators at the EPA database at go.usdatraining.com/I-WASTE.
    - Log on to the I-WASTE Tool and obtain a password if you do not currently have one.
    - Enter userid and password.
    - Choose treatment and disposal facilities button on the lower left.
    - Enter filter criteria such as “facility type (e.g. rendering, incinerators, or landfill)”
    - Enter State or EPA region, and click “View List of Facilities” button or map facilities.
Contact air authorities to verify operations are not in violation of their air permits.

If the facilities are compliant, contact them and determine if they will accept your livestock or poultry and meet some or all of your capacity needs.

If so, arrange for transport to off-site incineration facility for disposal.

- Determine if any permits are required for transport of infected carcasses.
- Determine type of transport vehicles required. If the waste must travel on public roads, it should be transported in closed, leak-proof trucks or dumpsters. Secondary containment may be needed, depending on the type of waste being transported. See University of Minnesota Risk Assessment.
- Work with Depopulation Group Supervisor within the Incident Command System to determine how many animals can be depopulated per day and how many trucks will be needed for transport per day, ensuring the rates are about equal. If not, arrange for leak-resistant, covered storage.
- Pre-identify transport routes to minimize exposure of susceptible premises.

If off-site incineration is an option see the Secure Transport and Off-Site Treatment/Burial training modules at go.usdatraining.com/Disposal and implement off-site incineration. If not, and you still need to dispose of animals, inform Operations Chief and discuss alternate strategies such as vaccination. Return to First Option and repeat cycle until all carcasses can be managed.
Overview of In-House Composting Process

Composting materials within enclosed structures may contain harmful levels of air contaminants. Before entering the structure wear appropriate personal protective equipment and maximize natural ventilation by opening the doors and curtains to all the houses containing compost piles. Allow enough time for the houses to air out before entering them. Close the doors and curtains after completing the temperature readings.

Use the buddy system. Entering a barn with active compost or dead birds requires a two-person team. One person, with a cell phone, stays outside the house to monitor the person inside. Before anyone enters the barn, the monitor writes down the location so it can be given quickly to a 911 dispatcher in case of an emergency.

If the person inside is overcome, the monitor immediately calls 911 for assistance. Under no circumstances does the monitor enter the barn without Self Contained Breathing Apparatus (SCBA). Do anything possible to increase ventilation inside the building while waiting for rescue personnel.
## Carcass Management: In-house Composting Checklist

1. **Based on the opinion of an animal mortality composting subject matter expert (SME) from the APHIS roster, are the site conditions suitable for in-house composting of the number of animals affected?**
   - See USDA Mortality Composting Protocol for Avian Influenza Infected Flocks (also at go.usdatraining.com/HPAI)
   - Poultry houses have sufficient interior space to maneuver composting equipment and construct windrows (e.g., enough open space and ceiling height to allow loaders to construct windrows 6-8 feet high and 12 feet wide. Houses with columns, such as double-deck houses, restrict such formations.)
   - Poultry houses are located in an area that is accessible by trucks delivering carbon source and equipment removing compost
   - Poultry houses can be secured against vandals, scavengers, and disease vectors such as wild birds

2. **If the poultry houses are suitable, consider the duration of time it takes to fully compost and determine if the following issues can be overcome:**
   - Personnel required to ensure proper construction, maintenance, and temperature monitoring of windrows.
   - Need for pest management.
   - Denial of use of poultry houses while composting (at least 30 days).

3. **If so, is there a sufficient local supply of carbon source such as wood chips (1-2 pounds carbon source per pound of biomass)?**
   - Check with local agencies and organizations to determine if stockpiles of carbon source are available (e.g., parks department and landfills). Ensure that the carbon source is free of any pests or pathogens which could threaten local species. (See Carbon Sources for Windrow Construction)

4. **If so, have you arranged for the necessary personnel, equipment and supplies to be delivered to the site?**
   - Mortality composting subject matter expert
   - Composting supplies and carbon source
   - Personal protective equipment
   - Cleaning and disinfecting (biosecurity) supplies
   - Hand tools
   - Heavy equipment (mid-size skid-steer loaders, tractors with bucket loaders)
   - Qualified equipment operators

5. **If in-house composting is an option, see In-House Composting training module at go.usdatraining.com/Disposal and implement composting. If not, continue to Second Option.**

*Developed by USDA, DHS, and the 3D IPT*
Job Aid: Overview of the HPAI Composting Process  

May 12, 2016

Note: The purpose of this document is to provide a summary of the USDA APHIS Mortality Composting Protocol for Avian Influenza Infected Flocks and is not a substitute for that document. All appendices referenced below can be found in that Protocol located at www.aphis.usda.gov/fadprep.

CONDUCTING THE FARM ASSESSMENT

In order to plan for windrow construction at the affected premises, a Farm Assessment is required. The Farm Assessment may be provided by the Site Manager or may be developed by a composting Subject Matter Expert (SME) recognized by APHIS. The following components found within the assessment must be completed.

- Evaluate the barn configuration to determine if space is adequate for windrow(s) construction within the poultry barns. If not, assess other on-site structures or outside compost sites (see Appendix A).
- Evaluate the type and quantity of infected materials to be composted, including
  - carcass: type, size, number, and condition;
  - in-barn manure/litter: volume, moisture content, and density;
  - stored manure/litter: volume, moisture content, and density;
  - routine mortality method, location, and physical condition of mortalities;
  - feed: quantity and location;
  - eggs: quantity and condition;
  - clean bedding; and
  - paper products.
- Calculate the amount of carbon needed for composting (see Appendix B).
- Evaluate premises for supplemental water and include the source and application method.
- Evaluate on farm equipment availability and determine any supplemental equipment needs.
- Ensure all overhead lines and poultry house equipment are removed or out of the way. Be sure all loose cords cables or hoses are secured so that they will not become entangled by equipment.
- Ensure ventilation is balanced to reduce the risk of disease transmission while maintaining air quality for worker safety.

ARRANGING FOR NECESSARY EQUIPMENT

Following a Farm Assessment, the SME coordinates with the Site Manager and requests additional resources from the Incident Management Team (IMT) Logistics Branch. The resource list includes, but is not limited to:

- skilled equipment operators and general laborers;
- skid loader(s), pay loaders, dump trucks, rakes, and scoops;
- sawdust, litter, wood shavings, active compost, woodchips, or other carbon material; and
- compost thermometers (36” or 48” stem length).

CONSTRUCTING COMPOST WINDROWS

When constructing compost windrows, the SME should ensure that the following key elements are incorporated into the construction of the compost windrows:

- windows formed outside of poultry houses are sited in consultation with State and local officials to minimize environmental impacts;
- windrows (finished dimensions not to exceed 6 to 8 feet high and 12 to 15 feet wide) are constructed on adequate and uniform base layer (10 to 15 inches thick) of sufficiently porous carbon material;
• base layer and windrow are not compacted with equipment;
• feed from the feed bins and pans is distributed evenly into the compost mix;
• good carcass to carbon contact is achieved by creating a core with a minimum of 1:1 mix volume of carcasses and other infected materials (manure, egg shells, feed, etc.) and carbon;
• windrows are constructed to ensure adequate distribution of moisture throughout; and
• windrows are capped with carbon material (minimum 8 to 12 inches thick) to ensure that no carcasses are exposed.

TEMPERATURE MONITORING

Once windrow construction has been approved by the SME, daily temperature monitoring for 14 days can begin following the standard operating procedure (SOP) for temperature monitoring (see Appendix D). Temperature data should be recorded on the temperature log (see Appendix E), or in a comparable electronic document. The health and safety of the individual conducting the temperature monitoring should be protected by following the ammonia safety procedures outlined in Appendix F, and any other safety procedures required by the Incident Command (IC) or employer.

TURNING THE WINDROWS

After the evaluation and approval of the temperature data collected during the initial 14-day compost cycle, the windrow is eligible for turning. The SME or appointed designee will signal approval using the Phase 1 Windrow Approval Checklist (see Appendix G). Unless obvious problems are noted (leachate, exposed birds, poorly mixed piles, or excessive vector activity), windrows should not be disturbed before the end of the 14-day period. Physical mixing or rebuilding of the windrows will require restarting the 14-day period. Adding or replacing the cap materials or placement of clean carbon sources around the windrow base will not require restarting of the 14-day period. Turning must provide homogenization of the core, base and cap materials, and windrows must maintain adequate porosity and structure after turning. Following a second successful 14-day compost period, the SME or appointed designee will signal approval for releasing the windrow from quarantine by using the Phase 2 Windrow Approval Checklist included in Appendix G. If soft tissue is observed on the windrow surface, a 2 to 4 inch carbonaceous cap needs to be applied. See Appendix H for turning equipment and methods.

TROUBLESHOOTING PROBLEMS

In the event that windrows fail to perform in the required manner, the following table offers some of the most common composting problems and possible solutions that may be implemented. The advice and council of an SME should be sought in identifying and prescribing remedies for underperforming compost processes.

<table>
<thead>
<tr>
<th>Problem</th>
<th>Issue</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Excessive flies or odor</td>

Note: The purpose of this document is to serve as a guide or script to follow when calling companies who may be able to provide carbon material for emergency mortality composting.

PLANNING THE CALL

The caller needs to be familiar with the Carbon Source Job Aid.

Use as reference during discussion:
- Carbon Source Job Aid
- Procuring DUNS and SAM numbers for federal contracting, or state contracting information.

IDENTIFY YOURSELF AND ASK FOR THE OWNER/MANAGER

Hello, I'm (name) with the (organization). We are preparing for potential animal disease outbreaks in our state and composting is one of our options for carcass disposal. (Stress this point)—There is no disease currently going on, this is only for planning purposes. To adequately compost, we will need wood chips, shavings, and similar carbon materials, and your company has been suggested as a potential supplier. We wanted to find out if you have this material and if you might be interested in providing it in an emergency? (If they are interested, what kind of materials can they provide?)

The material must meet certain specifications to be effective. Reference APHIS Carbon Source Job Aid, e-mail if possible. (If owner/manager can meet the specification, continue; otherwise thank them for their time and ask if they know any other potential suppliers, then end call.)

Depending on the size of an infected farm, we might need to order the material by the truckloads for delivery within 48 to 72 hours so the carcasses can be quickly composted. This is only for livestock and poultry. Transportation could be contracted if you do not have the vehicles to move large quantities of materials.

(If the owner/manager can meet the need, continue; if not, thank them for their time and ask if they know any other potential suppliers, then end call.)

We will not be able to guarantee that you will be contacted, and we are currently collecting this information for planning purposes only. Any order would be placed by contracting officials at the time of the emergency if funds are available. If you’re interested in helping, we could put you in

Developed by J. Davis, USDA, 2016
contact with someone that could give you more details on contracting with the state or federal
government. You would be paid fair market price for the materials and this would be negotiated at
the time of the emergency.

We hope that we would never have to face the situation in (their State), but if you’re interested,
may we add you to our list of potential suppliers? □ No □ Yes If yes, continue. If no, thank them
and ask if they have any other recommendations, and end call. ____________________________

Thank you for your help. We would like to verify we have your accurate contact information and
would like to ask a few questions, if that’s OK with you?

Provide (your contact information) for further questions or (their State or federal contact information).

Thank you for your help. (End the call.)
Mortality Composting: Carbon Sources for Windrow Construction

May 9, 2016

Please note: These procedures may be revised as the situation develops; this is a list of generally acceptable carbon sources for windrow composting of HPAI related mortalities. The carbon source resource needs for the premises, i.e. quantity and type, should be determined by a compost Subject Matter Expert and will depend on site-specific (typically poultry house-specific) conditions and circumstances.

Suitable carbon sources:
- Wood chips about 2” or less in size
- Wood shavings
- Yard/brush trimmings 2” or less in size
- Partially composted leaf and yard waste (still hot)
- Sawdust (not used alone)
- Chopped hay/straw
- Chopped corn stover
- Oat/Sunflower hulls
- Dry mammalian manure
- Ground pallets (2” or less) if fasteners have been removed
- Class A Biosolids, in accordance with local and state requirements for land application
- Other material listed in APHIS Composting Protocol or as recommended by APHIS-recognized Subject Matter Expert and approved for use on agricultural land by the state

Materials not suitable within a carbon source:
- Rocks
- Glass
- Plastic
- Large logs/branches
- Grass clippings >5%
- Ground construction and demolition debris (CDD)
- Regulated pests (Emerald ash borer, etc.)
- Rubber
- Metal/baling wire
- Chemicals
- Concrete
- Painted/pressure treated wood
- Soil/sand
- Carbon source with free liquid or excessive leachate

Mulch from yard trimmings/waste
- Wood chips
- Chopped corn stover
- Oat hulls

Mixed wood with logs/large lumber pieces
- Wood chips with rocks/gravel
- Construction demolition debris

Developed by USDA APHIS Composting Technical Team
Mortality Composting:
Pre-Compost Windrows for
Avian Influenza Infected Flocks

Please note: These procedures may be revised as the situation develops.

PRE-COMPOST WINDROWS (PREP PILES)

Applicability: This method can be used after poultry have been euthanized to stabilize the carcasses while awaiting arrival of a composting subject matter expert to guide construction of the final windrows.

Description: This method, which increases the amount of carbon material mixed within the windrow core, involves forming two pre-compost windrows, capping them, and then forming one final windrow at a later time. This is especially useful when dealing with large amounts of carcass material relative to litter, creating a significant C:N imbalance, or when additional carbon material will increase porosity. Forming pre-compost windrows also stabilizes the tissue and begins a heating process until a single windrow can be constructed.

BUILDING PRE-COMPOST WINDROWS

- Move litter and carcasses from along sidewalls and the center of the house, forming two pre-compost windrows extending the length of the house (see top right photo).
- Cap each windrow with 8–12 inches of suitable carbon material.

BUILDING FINAL WINDROW FROM TWO PRE-COMPOST WINDROWS

- In the center of the house, construct a 12–15 foot wide base that is 10–15 inches deep.
- Combine both capped pre-compost windrows onto the base, mixing litter, carcasses, and added carbon material.
- Cap the final windrow with 8–12 inches of suitable carbon material (see bottom right photo).

Developed by USDA APHIS Composting Technical Team
Mortality Composting:
Windrow Construction Protocol for Avian Influenza Infected Flocks

Please note: These procedures may be revised as the situation develops.

**TYPICAL WINDROW CONSTRUCTION PROTOCOL**

Three critical elements of windrow construction are: 1) a porous base layer, 2) a uniformly mixed windrow core, and 3) an adequate cap (see Figure 1). These steps may be done concurrently or as separate steps.

![Figure 1. Cross Section of Compost Windrow](image)

**WINDROW BASE CONSTRUCTION**

Before in-house composting, clear carcasses and litter from the windrow location(s) of the poultry house to create a 12–15 foot wide work area for construction of the windrow base(s). Distribute the material from on either side of the pathway. (See Appendix C for in-house variations.)

Before outside composting, an adequate site must be identified (see Appendix A). Site modifications and approval from State and local agencies may be required.

Using the largest loader possible, begin building the windrow base.

The windrow base should be 12–15 feet wide with a depth of 10 to 15 inches. Base will compress over time.

Carbon material for the base should be porous and bulky enough to allow adequate air flow into and through the windrow. Ideal materials for the base include bark mulch or coarse wood chips. Other acceptable materials include: straw, wood shavings, active compost, small grain hulls, and corn stover. Also, coarse woody material in excess of 2 inches in size should be avoided to ensure that the resulting compost can be land applied as a soil amendment.

If these materials are not available, poultry litter may be used for the windrow base if it is sufficiently dry, porous, and bulky.

To maintain the base’s porosity and to avoid compaction, do not drive equipment on the base.

*Developed by USDA APHIS Composting Technical Team*
CONSTRUCTION OF THE CORE

The windrow core should consist of a uniform mix of carcasses and litter. The easiest way to get a uniform mix throughout the windrow is to scoop litter and birds together in each bucket load and add it to the windrow in a manner that thoroughly mixes the contents of the bucket. If additional carbon material is needed, the material should support heat generation (i.e., composting). Suitable materials include fresh wood shavings, active compost, poultry litter, straw, corn stover, and small grain hulls. In many instances this material may need to be blended with the existing litter and carcasses to be suitable.

Any remaining feed should be blended and mixed with the carcasses and litter before windrow construction. Be sure to move infected material as little as possible.

The mix of carcasses and litter should be added from both sides of the windrow. This allows the operators to reach the center of the windrow and avoid compacting the base with the tires or tracks of the loader.

The windrow core should be constructed such that 1 foot of base material is exposed on both sides of the windrow.

Add water as needed.

The core should be dome-shaped and of sufficient height to include the litter and carcass mix from the area adjacent to the windrow. At this stage, the windrow height should not exceed 6 feet.

Continue building the core until all of the litter and carcasses have been placed on the base.

CAPPING THE WINDROW

Prior to capping the windrow, remove any carcasses that are near the edge of the windrow base and include them in the core of the windrow.

Cap the windrow with 8 to 12 inches of a suitable carbon material. Carbon material for the cap should prevent flies from contacting carcasses, serve as an insulating blanket, and allow air to flow out of the piles. This material may be finer in texture than the base. Suitable material includes poultry litter, small grain hulls, sawdust, new bedding, and wood chips. Straw, corn fodder, or similar material may also be suitable; however, experience has shown that these products can blow off the windrow and may need to be thicker to serve this purpose than other materials.

Ensure that the entire core is uniformly covered with cap material with no carcasses exposed.

Avoid compacting the windrow. Do not operate the loader’s tires or tracks onto the sides of the windrow while capping.

The completed windrow should be approximately 6 to 8 feet high.

IN-HOUSE COMPOSTING

Mortality Composting:
Temperature Monitoring Protocol of Avian Influenza Infected Flocks

May 9, 2016

Please note: These procedures may be revised as the situation develops.

TEMPERATURE MONITORING PROCEDURE

Monitor temperatures of the windrow daily at a minimum of 10 locations flagged by the Subject Matter Expert (SME). The temperature monitoring locations should be spaced equidistantly the length of each windrow. Take two temperature readings at each flagged location within a foot of the flag; one reading at a depth of 18 inches and another reading at a depth of 36 inches. To ensure consistent temperature monitoring to the same depth, mark the thermometer probe at 18 inches and 36 inches. Place the temperature probe ¾ of the way up the windrow at a 45 degree angle. Ideally, temperatures should be monitored by a single individual for consistency. Temperature probes should be calibrated before first use and weekly thereafter (see Calibration of Analog Thermometers Job Aid

Calibration dates can be recorded on the Composting Temperature Log, attached.

INSTRUCTIONS

➢ Turn on fans or open the doors and curtains to all the houses containing compost piles to allow them to air out and to maximize ventilation.

➢ USE THE BUDDY SYSTEM. Entering a barn with active compost or dead birds requires a two person team.

➢ Place the stem of the thermometer approximately 18 inches and then 36 inches into the compost pile half way up the pile at a 45 degree angle.

➢ Leave the thermometer at each depth and point for at least 60 seconds.

➢ Log the reading from the thermometer at each flag and at both depths.

➢ Compare readings to previous day's readings.

➢ After completing the house readings, close the doors and curtains.

➢ Calculate the average temperatures for each pile by averaging the 18-inch readings for all flags for that day then averaging the 36-inch readings for all flags for that day and noting the two averages on the Composting Temperature Log

➢ Windrows should reach an average temperature of 131°F for a minimum of 72 consecutive hours at both the 18 inch and 36 inch depths or be assessed by a SME for possible corrective measures.

➢ Disinfect the thermometer and return it to its protective case.

➢ Each thermometer will be kept at the respective premises being monitored. Do not take a thermometer from one premise to another.

➢ If by the third day after initial windrow construction, compost temperature averages remain below 100°F or greater than 160°F, a SME should be consulted immediately.

➢ During Phase 2, a SME should be consulted immediately if any monitoring location is consistently (more than 3 consecutive days) below 100°F or greater than 160°F.

Calibration Week 1 (Name): ___________________________ Date: _______________
Calibration Week 2 (Name): ___________________________ Date: _______________
Calibration Week 3 (Name): ___________________________ Date: _______________

Developed by USDA APHIS Composting Technical Team
IN-HOUSE COMPOSTING

Calibration of Analog Thermometers

March 22, 2016

ROUTINE CALIBRATION OF COMPOST THERMOMETERS MAINTAINS EQUIPMENT ACCURACY

The purpose of windrow composting of HPAI related poultry carcass mortality is inactivation of avian influenza virus. Compost pile temperature measurements are a critical indicator of effectiveness of the compost process for virus inactivation. Temperature monitoring is performed by a compost subject matter expert (SME), regulatory monitoring staff, contractors, or farm personnel. Accurately monitoring and recording daily temperatures is vital to demonstrating that the composting process meets time and temperature requirements designated by USDA-APHIS. *These time and temperature requirements must be met as part of the process to release quarantine on the infected premises.*

The calibration process described below is appropriate for most commercially available dial-type compost thermometers. Compost thermometers commonly in use for HPAI response are 36” or 48” length bimetal dial industrial compost thermometers (such as the 5/16” stem heavy duty, or 3/8” stem with ¼” fast response tip super duty) manufactured by Reotemp Instruments.

THE THERMOMETER SHOULD BE CALIBRATED BEFORE FIRST USE AND, AT A MINIMUM, WEEKLY

Calibration should also be performed if any of the following occurs:

♦ It is dropped on a hard surface or subjected to severe shock
♦ It is subjected to forces causing excessive pressure or bending of the stem
♦ It is subjected to prolonged vibration
♦ It is exposed to extreme temperatures outside the range of the dial
♦ The calibration screw on the back of the dial is turned accidentally

**Safety:** The pointed stem of the thermometer is very sharp. Take care when handling and use a protective sheath when the thermometer is not in use.

Note: *If the stem of the thermometer is bent or the dial is un-sealed or broken, the thermometer should be discarded and another procured. It is recommended that, where possible, thermometers be purchased with and fitted with a “probe handle” or “probe guard” for safer handling and protection of the stem and dial.*

*Developed by USDA APHIS Composting Technical Team*
**MATERIALS NEEDED TO PERFORM CALIBRATION:**

- Sturdy pail or bucket
- Cold water
- Ice (crushed or small cubed)
- Flathead screwdriver
- Compost temperature log or calibration form
- Pen or pencil

**CALIBRATION INSTRUCTIONS:**

1. Assemble a water bath of known temperature, typically an ice bath 32°F (0°C). Place enough ice in the bucket to have at least 6” depth, adding just enough water to fill spaces between the ice pieces. Let sit for one to several minutes.
2. Agitate (stir) the bath just before and occasionally during calibration.
3. Immerse thermometer tip at least 4” into bath, as the sensitive portion of the thermometer is the last 2-3” of the stem. Be sure tip does not touch sides or bottom of bucket.
4. Leave thermometer in the bath for at least one minute.

5. If the dial does not read 32°F, using the flathead screwdriver, turn the small (1/4”) hex screw head on the back of the dial case of the thermometer until the pointer is at 32°F. Turn the screw counter-clockwise to increase temperature or clockwise to decrease temperature.

6. When adjustment is complete, re-check the thermometer in ice water. Repeat adjustment if necessary.
7. Each time a thermometer is calibrated it is to be documented that calibration was completed. Information can be recorded on the compost temperature log or a separate calibration form. Include an equipment identifier, date, reference temperature (32°F), and name of the individual performing the calibration.
Mortality Composting:
Phase 1 Windrow Evaluation Checklist
Days 1-14 for Avian Influenza Infected Flocks

Please note: These procedures may be revised as the situation develops.

PHASE 1 WINDROW APPROVAL CHECKLIST

**Applicability:** This checklist is to be used 14 days after windrow construction to verify that they have been constructed in accordance with the protocol and have reached temperatures necessary for virus inactivation.

PHASE 1 RECOMMENDATIONS OF STATE ANIMAL HEALTH, APHIS OR IMT OFFICIAL:

☐ I have observed the windrows at this site and in my professional judgment they have been constructed consistent with the criteria outlined in the Mortality Composting Protocol for Avian Influenza Infected Flocks. Additionally, windrow temperatures have reached the average temperature of 131°F for a minimum of 72 consecutive hours. The 14-day initial composting cycle is complete.

Developed by USDA APHIS Composting Technical Team
I have observed the windrows at this site and in my professional judgment they have NOT been constructed consistent with the criteria outlined in the *Mortality Composting Protocol for Avian Influenza Infected Flocks*. The windrows should be evaluated by a composting Subject Matter Expert (SME) to recommend corrective actions if necessary.

Windrow temperatures have NOT reached the average temperature of 131°F for a minimum of 72 consecutive hours. The windrows should be evaluated by a composting SME to recommend corrective actions if necessary.

PLANNING FOR IN-HOUSE POULTRY COMPOSTING

1. Identify service providers for:
   a. Mortality composting. Personnel should be trained on operational procedures, composting procedures, and the proper disposal and composting of animal carcasses. Contact APHIS Disposal Cell for roster of Composting SMEs.
   b. Heavy equipment operations.
   c. Carbon source production and delivery (assume 2–3 pounds of carbon source per pound of carcass).

2. Identify regulatory requirements and obtain pre-approval.

3. Identify a facility that
   a. has sufficient space to maneuver composting equipment and construct windrows. The facility should contain enough open space and ceiling must be high enough to allow the loader to construct windrows 6 feet high and 12 feet wide. Facilities with columns, such as double-deck houses, restrict such formations;
   b. is located in an area that is accessible by the composting equipment. This facilitates the delivery of carbon source and compost removal; and
   c. offers access doors that can be secured against vandals, scavengers, or disease vectors.

4. Obtain all necessary equipment, supplies, materials, personnel, and services identified in the Site Specific Disposal Plan and as required by the Biosecurity and Health and Safety/PPE SOPs, such as PPE, carbon source, skid-steer or front-end loaders, long-stemmed thermometers, pH meters, bulk-density testing devices, and log books.

5. Ensure all compost team members are trained on proper procedures for composting infected carcasses, biosecurity procedures, work safety issues, and the use of PPE. If they are not, see below.

7. Identify a qualified disposal Contracting Officers Representative to oversee the composting operations.

---

12 Content and all photos in this attachment are courtesy of Cornell Waste Management Institute. http://cwmi.css.cornell.edu/composting.htm.

USDA FADPREP Disposal SOP
OPERATIONS FOR IN-HOUSE OR OUTDOOR POULTRY COMPOSTING

1. Don all required PPE as detailed in the Site-Specific Health and Safety/PPE Plan.

2. Select a site that is well drained and not subject to flooding. Keep piles away from homes and businesses and from water courses, sinkholes, seasonal seeps or other landscape features that indicate the area is hydrologically sensitive.

3. When implementing in-house composting the poultry house will be vented naturally but mechanical ventilation should be turned off.

4. Site cleanliness is an important aspect of composting; it deters scavengers, helps control odors, and helps maintain good neighbor relationships.

5. Push litter and feed off to the side of the barn. Lay an 10-15 inch deep bed of coarse wood chips, 8–12 feet wide (depending upon structure and equipment constraints) and as long as space permits.

6. Add a 12–15 inch layer of litter and birds, then cover with a 12–15 inch layer of wood chips or other carbon sources.

7. Add another layer of litter and birds until the windrow is two or three layers high and as long as needed.

8. If your birds and litter are not separate, put a carbon base down (as in step 4), add birds mixed with litter and bedding to 4-5 feet high and continue as follows.

9. Cover with 1-2 feet of wood chips or other carbon sources to create a bio-filer. The finished section should be 6–8 feet high.
11. Make sure all mortalities are well-covered to keep odors down, generate heat and keep vermin or unwanted animals out of the windrow.

12. Monitoring is the only activity that will occur. Temperature probes will be used to record temperatures and should range from 131°–150°F or 55°–65°C during most of this time period.

13. The primary process in-house, where it reaches thermophilic temperatures, will take 10–14 days. During this time, no turning, agitating, or active aeration should occur.

14. If litter is very dry, add moisture to the layers as you are building them. The compost feedstock should be at 30–40% moisture.

15. After the required time/temperature duration, windrows can be moved outside the buildings for the curing process. Testing for the presence of the disease will be required.
Procedures for In-House Composting of AI-Infected Poultry Carcasses

Preparation

If your poultry houses have enough ceiling clearance, in-house composting is a highly effective means to dispose of large numbers of poultry carcasses.

There are a number of steps you can take right now to prepare in the event of an outbreak.

- Obtain contact information for the proper authorities which may include: State veterinarian, poultry company personnel and university extension personnel.
- Identify any permits required to compost in your region especially those from APHIS and state/local environmental personnel.
- Determine the composting method best suited for your facility.
  - Mixing and Piling - ideal when carcasses are distributed more evenly over the litter surface. Less expensive than layering.
  - Layering - if depopulation concentrates carcasses in a small section of the house
  - Shredding and Piling - not preferred for highly pathogenic organisms
- Determine carbon source needs – This is the bulking agent used for moisture and odor control and as necessary ingredient for microbes to produce compost. Identify sources in advance.

Acceptable carbon sources include:
- Litter
- Silage
- Wood chips
- Corn husks
- Sawdust
- Bedding material
- Straw

Post Infection

Secure the infected site
- Rope off infected area and establish disinfection area
- Ensure disinfectant is contained and doesn’t run offsite or to surface or ground water
- Prohibit entry into infected area unless personnel are properly trained, fit tested, and wearing personal protective equipment

Identify existing mortality storage areas and remove possible contaminants
- Move any carcasses and infected organic materials inside the building on the secured infected site
- Clean and disinfect the mortality storage area to eliminate the pathogen

Evaluate the site
Assess housing and inventory available supplies, equipment, materials in order to enable planning for the disposal of carcasses. Compile information compiled about:
- Bird age, species, avg. weight
- Production type (cage, floor, outdoor)
- House type
- Litter depth, moisture and condition
- Depopulation method/location of carcasses
- Poultry house type and dimensions including ceiling height [Sufficient clearance for front loader to make window 4 to 6 feet high?]

Inventory/Supplies
At least one day prior to composting event, obtain required items, including:
- Personal protective equipment
- Monitoring equipment
- Mixing equipment
- Carbon source
- Turning equipment

Till litter
If carcasses are confined to a portion of house and caking is extensive, till the litter in the house in order to enhance composting.

Final Preparation for Composting
- Let birds consume all feed
- Raise the feeder and drinker lines
- Depopulate

Carbon Source Calculation Equations

Pounds of Broiler Meat = (# of birds) * (Avg weight )

Area of House = Length x width of house

Total Required Litter = \( \frac{\text{Pounds Broiler Meat \times 0.8}}{\text{Area of House}} \)

*or 1.0 for large turkeys or layering compost method

Average Litter Depth = \( \frac{\text{Sum litter depths in each part of house}}{\text{Number of parts of house}} \)

*converted to same units as length/width of house

Litter Available = (Avg litter depth) * (area of house)

Required Carbon Source Material = (Total litter required) – (litter available)
### Building Windrows

**Address health concerns**
- Provide dust control measures if needed.
- Ventilate composting byproducts by opening one of the curtains part way or using one of the smaller ventilation fans on the building – filter ventilation to avoid pathogen spread.

**Select composting method** – See Preparation topic

**Mixing and piling method**
1. Remove carcasses one bucket-width wide from along the sidewalls and spread them evenly in the center of the house.*
2. Starting with a 3-inch minimum base of clean carbon source, use feed line as a guide and mix the carcasses with the carbon source to start windrow.
3. Continue rolling materials together to form a windrow 10-12 ft. wide or twice the reach of your loader so you can access the middle.
4. Cover with 6-12 inches of litter or sawdust over all carcasses and bird parts.
   - If litter is inadequate and supplemental sawdust is required, this step is not required.

**Layering method**
1. Create a 3-inch thick base of clean carbon source. Make the base 10-12 feet wide or twice the reach of your loader so you can access the middle.
2. Place carcasses on top of base using loader.
3. Spread carcasses evenly with rake or pitchfork until the carcass layer is 8-10 inches thick.
4. Repeat layering procedure until the pile is 4-6 feet high, depending on height of ceiling.
5. Cover with 6-8 inch layer of clean carbon source with a foot overlap on the sides over all material.

**Treat Excess Contaminated Litter**
Place excess contaminated litter in windrows to compost and deactivate pathogens.

**Disinfect tools and site**
- Disinfect all tools and equipment from house after forming windrows
- Disinfect site according to approved disinfection procedures

**Turn up heat in poultry house**
Turn up to 100F for 1-3 days to expedite composting process and eliminate the pathogens on surfaces.

### Monitoring and Turning

**Temperature Monitoring**
1. Use a 3-foot long digital temperature probe connected to a data logger to take daily readings. Digital recording thermometers reduce the need to enter the building to once a week.
2. Use at least 2 probes per windrow. Best to have 1 at outside edge and 1 in center of windrow every 10 ft.
3. Put tip of thermometer in contact with carbon source layer at the center of the windrow.
   - **NOTE:** If the temperature reaches 180F, monitor and/or turn the hotspot to prevent fire hazard.

**Turning windrows**
1. Turn windrows when temperature drops below 125F.
2. Turn inside house, shifting windrows toward ends.
3. Scraper along edges of the turned windrow and deposit material on top.
4. Cap with at least 4 inches carbon source to cover any exposed tissue.
5. Cover pile with compost fleece or another suitable porous fabric to protect from scavengers. Do not use airtight cover as this will cause condensation and may negatively affect the composting process.
6. Secure the material using dirt and soil on the edges or some other means to restrict scavengers access.

<table>

<td>10 days</td>
<td>20 days</td>
</tr>
<tr>
<td>10lbs</td>
<td>16 days</td>
<td>26 days</td>
</tr>
</tbody>
</table>

**Post-turning monitoring**
2-3 weeks after 1<sup>st</sup> turning, test compost for maturity using a test kit such as Solvita.

### Disposal
2-3 weeks after the 1<sup>st</sup> turning, compost may be land applied and incorporated in accordance with the nutrient management plan for the soil and crop or hay. Total time may vary by locality and season depending on the temperature. The cooler the weather, the longer this process takes. If the temperature is below freezing, you may have to wait until spring before compost is assumed to be pathogen-free. If no growers are willing to take the mature compost, it should be landfilled as a nonhazardous waste.
## Outdoor Composting Checklist

**Identify a suitable site on premises or in a centralized location in accordance with the checklist items below.**

- If off-site consider the need for secure transport

**Based on approval of the state environmental agency and the composting SME from the APHIS roster, are the site conditions suitable for composting the number of animals affected?**

- See USDA Mortality Composting Protocol for Avian Influenza Infected Flocks (also at go.usatRAINING.com/HPAI)

- Adequate land area to build compost piles (assume (237) 1000-pound cows per acre, (1,185) 200-pound swine or sheep per acre, or (47,500) 5-pound poultry per acre).

- Required distance from water wells, surface water bodies (lakes, streams, rivers, etc.), sinkholes, seasonal seeps or other landscape features that indicate the area is hydrologically sensitive, based on guidance from state environmental officials.

- Consider all groundwater pathways including the presence of drain tiles, soil characteristics, depth to groundwater, use of groundwater etc.

- Located away from neighbors and/or out of sight.

- Located downwind from neighbors and/or houses.

- Located away from environmentally-sensitive areas.

- Located close to the livestock or poultry facility or have clear access for transport.

- Clear of overhead utility lines.

- Void of excess water.

- Located on a gentle slope (1%-3%) so there will be no water ponding.

- Consider the need for an impermeable base and/or protective cover to prevent leachate generation and migration.

**If the site is suitable, consider the duration of time it takes to fully compost and determine if the following issues can be overcome:**

- Personnel required to ensure proper construction, maintenance, and temperature monitoring of windrows.

- Need for pest management.

- Potential for extreme weather (e.g., hurricane) to disturb pile.

- Denial of use of land area while composting (minimum 30 days).

**If so, is there a sufficient local supply of carbon source such as wood chips (1-2 pounds carbon source per pound of biomass)?**

- Check with local agencies and organizations to determine if stockpiles of carbon source are available (e.g., parks department and landfills). Ensure that the carbon source is free of any pests or pathogens which could threaten local species. See Carbon Sources for Windrow Construction.
If so, have you arranged for the necessary equipment and supplies to be delivered to the site?

- Personnel
- Composting supplies and carbon source
- Personal protective equipment
- Cleaning and disinfecting (biosecurity) supplies
- Hand tools
- Heavy equipment (mid-size skid-steer loaders, tractors with bucket loaders, trucks, containers and covers if transporting, leak-resistant material for lining carcass transport containers)

If composting is an option see Outdoor Composting training module at [go.usdatraining.com/Disposal](http://go.usdatraining.com/Disposal) and implement composting. If not, continue to Third Option.
PLANNING FOR OUTDOOR COMPOSTING FOR LIVESTOCK OTHER THAN POULTRY

1. Identify service providers for:
   b. Heavy equipment operations.
   c. Carbon source production and delivery (assume 2–3 pounds of carbon source per pound of carcass). See Carbon Sources for Windrow Construction

2. Identify regulatory requirements and obtain pre-approval from state environmental agency.

3. Identify a composting site that is
   a. large enough to accommodate the windrows (assume 24 feet wide and 6 feet high by required length plus staging and access areas);
   b. located away from neighbors and out of sight;
   c. at least 200 feet from drinking water wells, surface water, and environmentally sensitive areas;
   d. downwind of homes and other dwellings;
   e. accessible in all weather;
   f. clear of underground and overhead utilities;
   g. not interfering with traffic;
   h. on a crowned grade where storm water will not accumulate;
   i. void of excess water; and
   j. capable of being dedicated to composting for several months.

4. Obtain all necessary equipment, supplies, materials, personnel, and services identified in the Site Specific Disposal Plan and as required by the Biosecurity and Health and Safety/PPE SOPs, such as PPE, carbon source, skid-steer or front-end loaders, long-stemmed thermometers, pH meters, bulk-density testing devices, and log books.

5. Ensure all compost team members are trained on proper procedures for composting infected carcasses, biosecurity procedures, work safety issues, and the use of PPE. If not,

7. Identify a qualified disposal Contracting Officers Representative to oversee the composting operations.
OUTDOOR COMPOSTING

STANDARD OPERATING PROCEDURES: 14. DISPOSAL

Attachment 14.A Composting

OPERATIONS FOR OUTDOOR COMPOSTING FOR LIVESTOCK OTHER THAN POULTRY

1. Don all required PPE as detailed in the Site-Specific Health and Safety/PPE Plan.

2. Select site that is well drained, at least 200 feet from water courses, sinkholes, seasonal seeps or other landscape features that indicate the area is hydrologically sensitive.

3. Fence the area if desired, and install measures to prevent water run-on and run-off if needed.

4. Construct an impermeable pad if excess leachate production is a concern to the approving authority. The pad could consist of a low-permeability soil base, pavement, or a suitable liner material beneath the pile if the liner will not cause the compost material to slip during inclement weather.

5. Place a 24-inch bed of bulky, absorbent organic material such as 3-inch wood chips over the pad. Ensure the base is large enough to allow for 2-foot clearance around the carcass.

6. Lay animal in the center of the bed. Lance the rumen to avoid bloating and possible explosion. Explosive release of gases can result in odor problems and it will blow the cover material off the composting carcass.

7. Cover carcass with dry, high-carbon material, old silage, sawdust or dry stall bedding (some semi-solid manure will expedite the process). Do NOT stack medium-sized, large, or very large carcasses on top of one another. For young animals, layer mortalities no more than 1 foot thick with a minimum of 2 feet of carbon material between layers.

Adapted from Cornell Waste Management Institute
8. Let sit for several months, then check to see if carcasses are fully degraded. Do not turn piles for at least 3 months.

9. Remove large bones before using the finished compost.

10. After building the compost piles, disinfect all tools, equipment and other items that may harbor pathogens, and maintain site cleanliness to deter scavengers, control odors, and help good neighbor relations.

11. Maintain a log of temperature, moisture, content, odor, vectors (any unwanted animals), leachate (liquid that comes out of the pile), spills and other unexpected events.

Adapted from Cornell Waste Management Institute
12. Monitor the internal compost pile temperatures daily with 3–4 foot long compost thermometers. The optimal temperature range for composting is between 104°F and 140°F (40°C and 60°C). During periods of extremely cold weather, piles may need to be larger than usual to minimize surface cooling. As decomposition slows, temperatures will gradually drop and remain within a few degrees of ambient air temperature. Don appropriate PPE equipment such as disposable gloves.
   a. Insert a temperature probe carefully and straight down into each quadrant of the pile to allow daily and weekly monitoring of internal temperatures at depths of 10, 20, 30, and 40 inches.
   b. Use the averages to represent the compost pile temperature.

13. If the compost pile does not rise to expected temperature levels within the first 2 weeks of composting, evaluate the initial pile formulation for proper carbon-to-nitrogen ratio (30:1) and the mixture of co-composting materials and carcasses.

14. If building an aerated static pile, the pile must be insulated (covered with a layer of bulking material or finished compost) and maintained at a temperature of not less than 131°F (55°C) for at least 3 consecutive days, monitored 6–8 inches from the top of the pile, to meet pathogen reduction standards typically used for land-applied sewage sludge.

15. Periodically test the moisture content of the compost. Use analytical equipment or the hand-squeeze method. For the hand-squeeze method:
   a. Don appropriate PPE (see the Health and Safety/PPE SOP).
   b. Squeeze a handful of compost material firmly several times to form a ball.
   c. The characteristics of the ball indicates the moisture content:
      i. If it falls apart, the moisture content is much less than 50 percent.
      ii. If it remains intact after being gently bounced three or four times, it is nearly 50 percent.
      iii. If the ball texture is slimy with a musty, soil-like odor and liquid squeezes out, the moisture content is more than 50 percent.
   d. If the moisture content is low and the pile temperature is very high (150°F), rake back the compost cover layer (up to 1 foot) and add enough water to bring the moisture content in the pile up to 50 percent.
   e. If liquid begins to leach out of the pile, spread an absorbent organic material such as sawdust around the pile.

16. Thoroughly clean and disinfect all of the disposal equipment. See the C&D and Biosecurity SOPs.

17. When the compost is finished (typically 4–9 months for a static mortality compost pile, depending on weather and other conditions), it can be used for
   a. a base for the next compost pile,
   b. land application on non-edible crops, and
   c. landfill daily cover.
# Procedures for Outdoor Composting of AI-Infected Poultry Carcasses

## Determine Compost Site Availability

<table>
<thead>
<tr>
<th>Space needed</th>
</tr>
</thead>
<tbody>
<tr>
<td>✓ Windrow composting</td>
</tr>
<tr>
<td>✓ Buffer width = 6 feet on each side (12 feet total)</td>
</tr>
<tr>
<td>✓ Total width = 24 feet</td>
</tr>
<tr>
<td>✓ Height = 6 feet</td>
</tr>
<tr>
<td>✓ Length = 1 foot per 300 lbs</td>
</tr>
<tr>
<td>✓ Bin composting</td>
</tr>
<tr>
<td>✓ Impractical for large numbers of animals</td>
</tr>
<tr>
<td>✓ Usually 160 ft³ needed for every 1000 lb of animals</td>
</tr>
</tbody>
</table>

### Area should be:
- Located away from neighbors and/or out of sight
- Located downwind from neighbors and/or house
- Close to barn or ability to transport
- Void of excess water
- Clear of underground and overhead utility lines
- Clear of surface water and environmentally sensitive areas
- Can be out of commission (for crops, pasture, etc.) for a given period of time

## Logistics (Cont.)

### Conduct farm evaluation
- Inventory available supplies, equipment, materials
- Collect site specific data
- Bird species and age
- Average bird weights
- Production type
- Litter depth in each part of the house
- Location of carcasses
- Litter moisture and condition
- Ability to remove carcasses
- Number of avian carcasses
- Least material/handling needs
- Determine carbon source needs
  - Pounds of broiler meat = number of birds in house x average weight of bird
  - Total litter required = pounds broiler meat/area of windrow or bin planned x 2.5 – 3 lbs. of carbon
  - Average litter depth = sum of litter depths in each part of house/number of parts of house
  - Litter available = average litter depth x area of house
  - Amount of carbon material to obtain = total litter required – litter available
  - Amount of carbon material to obtain (in cubic yards) = lbs needed x (1/bulk density)

### Logistics
- Determine location of windrow or bin
- Identify an area that is sensitive to the surroundings
- Consider location of drinking water supplies
- Close to material that will be composted and/or ability to transport compost without causing contamination in all weather conditions with minimal interference with other operations and traffic
- Avoid sites where excess water will enter
- Does not interfere with underground or overhead utilities
- Make sure the land is able to be out of commission for the entire compost period
- Seldom is it possible to find a site that is ideal in all of the factors—select the location that will have the least impact
- Choose composting method
  - Layering: if depopulation concentrates carcasses in a small section of the house
  - Mixing and piling: Where carcasses are distributed more evenly over the litter service; least labor and cost
  - Shredding and piling: This method is not recommended for highly pathogenic organisms, and should be avoided when composting birds infected with HPAI
- Determine security needs
  - Can compost pile be protected from vandals, scavengers, and disease vectors?
  - Dust and wind must be taken into account
- Obtain resources
  - Personnel
  - Supplies: carbon source, PPE, hand tools, personal needs
  - Equipment: loader, truck, pressure washer, dumpster, compost bag equipment
- Prepare for composting
  - Let birds consume all feed
  - Raise the feeders and drinking lines
  - Depopulate
- Transport
  - Lay polyethylene liner onto the ground outside house where truck will be loaded
  - Load mortalities onto truck with a front loader if possible, or else load manually
  - Minimize dust generation during loading
  - Cover truck to seal carcasses and material in and prevent any material from escaping
  - Transport to windrow site and unload onto site of compost pile
  - After transporting, dispose of plastic
  - After last load, thoroughly disinfect the truck
### Composting Birds and Byproducts

#### Prepare the site
- For bin composting, the bin should be constructed from any material that will confine the compost pile material and resist lateral loads
- Lay down a layer of plastic the width and length of your anticipated windrow or on the bottom of your constructed bin
- Lay down 12-24 inches of carbon source as a base (use thicker end of range if low evaporation and high precipitation)

#### Till litter
- If euthanized carcasses are confined to a portion of the house and caking is extensive, tilling the litter in the house prior to building windrows will enhance composting, which prevents leachate and improves oxygen entry into the pile

#### Build compost units (windrows)
- Mixing and piling method: method used if no additional carbon source is needed; involves mixing the carcasses with the existing litter base
- Layering method: leave no carcasses or bird parts exposed
- Shredding and piling method: not recommended for use with HPAI; may create increased risk of exposure to virus and cause increased utilization of equipment that then needs to be disinfected

#### Byproducts
- Contaminated litter: place excess contaminated litter in windrows to compost and deactivate pathogens
- Feed: place excess contaminated litter in windrows to compost and deactivate pathogens

### Finishing the Site
- Cover windrow with compost fleece or another suitable porous fabric to protect from scavengers; do not use a cover that does not allow some air to circulate as this will cause condensation and may negatively affect the composting process
- Secure the material using dirt and soil on the edges or some other means to restrict scavengers from accessing the windrows

### After Composting

#### Disinfection
- Disinfect all tools and equipment used after forming windrows
- Disinfect house

#### Maintenance
- Monitoring
  - Temperature
  - Viral
  - Vector
  - Moisture
- Turning
  - Can relocate the pile to another site or another bin or simply turn in place
  - Turn compost in place by shifting windrows towards the ends
  - Scrape along the edges of the turned windrow and deposit material on the pile
  - If the pile is moved, pick up the material and drop in a cascading manner—do not merely push the material from one place to another
  - Add water when needed
  - Cap the turned pile with a minimum of 4 inches of litter or sawdust to cover any exposed tissue on the surface
  - Re-cover with appropriate cover
  - Continue to monitor temperature

### Disposal
- Land application
- Landfilled
- Stored and aged

---

*USDA APHIS online Emergency Management Tools, 2007.*
Carcass Management: Open Air Burning Checklist

☐ Will local and state agencies allow open burning at the site?
  - Local Fire Department
  - State Department of Agriculture, Animal Health
  - State Department of Environment or Natural Resources
  - USDA-APHIS
  - USEPA

☐ Will open burning release air pollutants in excess of public health standards?
  - If so, can the permit conditions, such as measures to control the spread of fire, distance to occupied buildings etc. be met?
    - What environmental testing (e.g., water, ash, soils) are required and at what frequency?
    - How and where would the ash be disposed of?
    - Are weather conditions (e.g., wind and drought) suitable for open air burning?

☐ If so, will burning be publically unacceptable?
  - If so, have you arranged for the necessary personnel, equipment and supplies to be delivered to the site?
    - Adequate source of combustible material and fuel to keep the fire going. Verify that type of fuel is acceptable to regulatory agencies.
    - Other equipment including mechanical chains and lifting equipment.
    - Personnel properly trained in the use of this equipment.
    - Fire safety equipment also should be readily available.

☐ If open air burning is an option, see On-Site Treatment/Burial training module at go.usdatraining.com/aphis_tools and implement on-site open air burning. If not, continue to Fourth Option.
# Procedure for Open Air Burning of AI Infected Poultry Carcasses

<table>
<thead>
<tr>
<th>Open Air Burning</th>
<th>Advantages</th>
</tr>
</thead>
<tbody>
<tr>
<td>✓ Open-air burning involves combustion of waste at high temperatures, converting the waste into heat, gaseous emissions, and ash</td>
<td>✓ Combines sterilization and carcass destruction into one operation</td>
</tr>
<tr>
<td>✓ The gaseous emissions are vented directly into the atmosphere in the human breathing zone without passing through a stack or chimney</td>
<td>✓ Can be relatively inexpensive to construct</td>
</tr>
<tr>
<td>✓ Open-air burning includes burning carcasses in open fields, and on combustible open heaps, or pyres</td>
<td>✓ Can be used anywhere a permit can be obtained and there is sufficient distance from other combustible materials</td>
</tr>
<tr>
<td>✓ On-farm preprocessing may be required prior to open-air burning, which could include the grinding of carcasses which can be transported in sealed containers, or fermentation or freezing</td>
<td>✓ No specialized equipment or personnel are needed</td>
</tr>
<tr>
<td>✓ Open-air burning operations are strictly regulated—a permit is usually required to perform open-air burning, if it is allowed at all</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Disadvantages</th>
</tr>
</thead>
<tbody>
<tr>
<td>✓ Can be inefficient and time-consuming</td>
</tr>
<tr>
<td>✓ Can be difficult to accomplish because of the high water content of carcasses</td>
</tr>
<tr>
<td>✓ May cause significant air emissions</td>
</tr>
<tr>
<td>✓ Dependent on favorable weather conditions</td>
</tr>
<tr>
<td>✓ Can spread pathogens by dispersing partially-combusted particles into the air</td>
</tr>
<tr>
<td>✓ Labor and fuel intensive</td>
</tr>
<tr>
<td>✓ Can generate significant public opposition which may make obtaining a permit difficult</td>
</tr>
</tbody>
</table>
This method involves burning on open land and above ground, in a pit, or on pyres.

**Planning**

1. Obtain approval from state environmental agency.

2. Calculate the amount of material required to accomplish the open-air burning. One adult bovine carcass is equivalent to five finishing pigs or five adult sheep. One adult bovine carcass will require
   
   a. 3 bales of straw or hay,
   
   b. 3 pieces of untreated heavy lumber,
   
   c. 50 pounds of kindling wood,
   
   d. 100 pounds of coal pieces that are 6–8 inches in diameter, and
   
   e. 1 gallon of liquid fuel. Do not use gasoline. The type and amount of fuel used for incineration will be influenced by local fuel availability and conditions. For effective burning, fuel should be as dry as possible.

3. Other equipment includes mechanical chains and lifting equipment. Identify personnel properly trained in the use of this equipment. Fire safety equipment also should be readily available.

4. Build a fire bed that is perpendicular to the prevailing wind.

**Operations**

1. Don all required PPE detailed in the Site-Specific Health and Safety/PPE Plan.

2. Prepare the bed:
   
   a. Stake out and fence the selected burning site for the fire-bed construction.
   
   b. Allow a fire-bed length of 3 feet for each adult cattle carcass, five swine carcasses, or five sheep carcasses. The team may find it helpful to convert the number of carcasses in need of disposal into bovine-equivalent carcasses as seen in Table 14.F-1.17

```
Table 14.F-1. Estimating Bovine—Equivalent Carcasses

<table>
<thead>
<tr>
<th>Animal</th>
<th>Bovine Equivalent Carcasses</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 adult cow or bull</td>
<td>1 bovine-equivalent carcass</td>
</tr>
<tr>
<td>5 adult swine</td>
<td>1 bovine-equivalent carcass</td>
</tr>
<tr>
<td>5 adult sheep</td>
<td>1 bovine-equivalent carcass</td>
</tr>
</tbody>
</table>
```

16 Recommended incineration materials include straw or hay, untreated heavy timber, kindling wood, coal, and liquid fuel.

17 To estimate the number of bovine-equivalent carcasses, first list the number and species of carcasses to be incinerated, then convert these figures into a number representing bovine-equivalent carcasses.
c. Lay three rectangular rows of straw or hay bales lengthwise along the line of the fire bed. Rows should be 12 inches apart and each bale should be separated by a 12-inch gap.

d. Place loose straw in the spaces between the rows and bales to provide natural air flow.

e. Place large pieces of lumber lengthwise on top of each row. Distribute large and medium-sized pieces of lumber across the fire bed, leaving 6 to 12 inches of space between them.

f. Place small kindling wood on the fire bed and cover loosely with straw.

g. Spread 6- to 8-inch-diameter coal evenly at the rate of 500 pounds per square yard, or use a liquid field such as diesel or furnace oil over the wood mixture to make a level bed.

h. Lay the carcasses on the fire bed.

i. Position carcasses on their backs with their feet in the air and alternately head to tail.

j. Two goats, sheep, or swine carcasses can be placed on top of each bovine carcass and burned without additional fuel.

k. Place loose straw on top of the carcasses and all spaces in between.

l. Spray liquid fuel over the fire bed with a pump, or use sprinkling cans or buckets.

m. Soak rags in kerosene oil or waste oil and place them every 30 feet along the fire bed for a better and more harmonized ignition.

n. Make sure that people and equipment are at least 25 feet from the burning pile.

o. Have fire equipment readily available.

p. Ignite the fire bed.

q. Occasionally stir the burning pile with front-end loaders.

r. Add more fuel as needed.

s. Bury the ash after all carcasses have been burned completely and the fire has been extinguished.

3. Thoroughly clean and disinfect all disposal equipment.

   See the Cleaning and Disinfection SOP: go.usdatraining.com/SOP_CD and the Biosecurity SOP:
   go.usdatraining.com/SOP_Biosecurity
## Carcass Management: On-Site Burial Checklist

1. **Will state environmental agency permit burial at the site?**
   - Consider soil suitability (see USDA NRCS online Web Soil Survey at [go.usdatraining.com/WSS](http://go.usdatraining.com/WSS) based on guidance from state environmental officials?)
   - Consider potential for leachate to contaminate groundwater
   - Consider all groundwater pathways including the presence of drain tiles, soil characteristics, depth to groundwater, use of groundwater etc.
   - Consider potential for the burial site to create a stability or explosion hazard in nearby structures from production of methane.

2. **If so, is adequate land available for on-site burial?** (assume 1.42 acres per 1000 half-ton cows, 0.28 acres per 1000 swine or sheep, and 0.01 acres per 1000 poultry)

3. **If so, will land owner accept on-site burial, associated environmental liabilities, and potential loss of property value or use?**

4. **If on-site burial is an option, see the On-Site Treatment/Burial training module at [go.usdatraining.com/Disposal](http://go.usdatraining.com/Disposal) and implement on-site burial. If not, continue to Fifth Option.**

**Developed by USDA, DHS, and the 3D IPT**
Why is nitrogen a problem?

- EPA standard for nitrates in drinking water is 10.0 mg/L
- Carcass burial sites generate over 1000 times the standard
- Causes Methemoglobinemia (blue baby syndrome) which can be fatal to infants
- Toxic to aquatic life
- Depletes dissolved oxygen in receiving waters
- Stimulates aquatic plant growth (eutrophication)

Developed by L.P. Miller, USDA, 2014
### Land Area or Excavation Volume Required for Trench Burial

<table>
<thead>

<td>1 bovine = 40 broiler chickens (market-ready weight)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Planning

1. Review State and local regulations regarding burial. Individual States regulate the parameters for burial (e.g., quantity of carcasses, depth to water table, and distance to wells, surface water, and property lines).

2. Obtain information from the USDA NRCS Web Soil Survey such as soil maps, drainage, and seasonal water table data.

3. If the Web Soil Survey data indicates the site is suitable for carcass burial, obtain the services of a qualified environmental professional such as a Professional Geologist or Professional Engineer to collect at least three soil borings of the site to the water table. Trench burial has the potential to impact groundwater and generate offensive odors, requiring the water table to be deep and the soil impermeable. Using the soil logs, perform hydrogeological and contaminant transport modeling to assess the likelihood of the burial site contaminating drinking water aquifers.

4. Consult with appropriate State regulatory agencies about permits for potential sites before initiating operations.

5. Verify the site is large enough for on-site burial of the carcasses based on Attachment 14.I Land Area or Excavation Volume Required for Trench Burial, and the FAD/PReP Guidelines: Disposal (go.usdatraining.com/SOP_disposal).

6. Verify the site is accessible to carcass hauling trucks and heavy equipment.

7. Design the excavation size, depth, and side slope angles to prevent cave-ins.

8. Prepare and maintain a list of names and contact information for heavy machinery operators, fire department personnel, law enforcement, public works departments, departments of transportation, and regulatory agencies.

9. Contract with local heavy equipment suppliers and operators to deliver, operate, fuel, and maintain needed heavy equipment. Contract for carcass storage equipment and/or services if needed.

10. Ensure that personnel who will be operating the heavy equipment are properly certified in the use of the equipment.

11. Train disposal personnel on safety, biosecurity, and operational procedures in accordance with the Site Specific Plan.

Operations

1. Obtain all appropriate permits and approvals, including landowner’s permission and acceptance of long-term environmental liability, to begin burial.

---

2. Don all required PPE as detailed in the Site-Specific Health and Safety/PPE Plan.

3. Fence and stake the burial site.

4. Obtain the heavy equipment and machinery (backhoe, scraper, bulldozer, or other equipment) required for excavating.

5. Excavate the appropriate sized trench based on the excavation design parameters.

6. Puncture/vent the carcasses by stabbing the area posterior to the ribs and the thoracic and abdominal cavities, on the left side for ruminants.

7. Place carcasses in the trench.

8. Cover the carcasses with the excavated earth, being sure to grade the surface soil to facilitate runoff.

9. Seed the surface of the excavated area to minimize soil erosion.

10. Thoroughly clean and disinfect all of the disposal equipment. See the Cleaning and Disinfection SOP: go.usdatraining.com/SOP_CD and the Biosecurity SOP: go.usdatraining.com/SOP_Biosecurity

11. Regularly inspect and maintain the site by adding additional backfill to prevent pooling of water if necessary.

12. Highly recommended: monitor groundwater quality down gradient of the burial site(s) to ensure the ongoing safety of ground water.

**Note on Mass Burial**

Mass burial involves collecting carcasses from multiple affected premises and placing them in a large burial unit. The disposal unit must meet the criteria for a Subtitle D landfill, including leachate and landfill gas collection and management systems. During the 2001 FMD outbreak in the UK, approximately 20 percent (1.3 million carcasses) of FMD-infected carcasses were disposed using mass burial. Siting, permitting, designing, and constructing a Subtitle D landfill requires extensive site assessment, professional engineering design, and rigorous quality control during construction. The process takes a significant amount of time and funds, and the closed disposal unit requires long-term monitoring and acceptance of future environmental liability by the property owner. It is likely more cost-effective and efficient to establish an agreement with an existing Subtitle D landfill than to site, permit, design, and build a new one in the face of an emergency.
Carcass Management: Mobile Treatment Checklist

- Contact all appropriate mobile treatment technology vendors.
  - Verify the units are available for deployment to your site.
  - Verify your ability to meet all site/utility requirements.
  - Verify units can be fully disinfected after use.
  - Verify the units have adequate capacity to meet your needs.
  - If the capacity is less than needed, can the carcasses be stored/refrigerated while awaiting disposal?
  - Verify the availability of skilled operators and spare parts to keep the units operational.
  - Verify the unit can be set-up on the site (e.g., the site has appropriate grading).

- If so, is the technology permitted by the state environmental agency?

- If so, can the permit conditions be met?

- If so, can the process byproducts be readily disposed?

- If mobile treatment is an option, see On-Site Treatment/Burial training module at go.usdatraining.com/Disposal and implement. If not, continue to Sixth Option.
Overview of Mobile Treatment Technologies

Mobile treatment technologies can offer alternative, innovative, and immediate approaches to disposing of animal carcasses on-site, particularly in response to emergency situations. There are several types defined below:

- **INCINERATION**
  - **Air-curtain incineration:** blowing high velocity air across and down at an optimum angle into a firebox pit, creating an air curtain on top and a rotational turbulence within the firebox
  - **Gasification:** the waste mass is destroyed in multiple chambers including a primary (combustion) chamber followed by a secondary (gasification)

- **RENDERING**
  - The process of converting animal carcasses into carcass meal (protein-based solids), melted fat or tallow, and water

- **ALKALINE HYDROLYSIS**
  - Involves processing carcasses at high temperature, high pressure, and high pH to convert the proteins, nucleic acids, and lipids of the tissues to a sterile aqueous solution and solid by-products

- **STEAM OR MICROWAVE STERILIZATION**
  - Uses the direct application of steam or multiple, high-energy microwave generators to treat the disposal waste

### ADVANTAGES
- Easy to implement due to portability of units
- Inactivates pathogens
- Reduces the risk of disease spread due to limited movement and limited handling of infected material
- Environmentally favorable
- Self-contained units are generally acceptable to the public

### DISADVANTAGES
- Availability of resources and equipment may be limited
- Accessibility to equipment may be impeded depending on vendor proximity to the on-site location
- May need specially skilled operators who can keep equipment running and who are trained in biosafety and biosecurity
- Level, paved areas may be needed to set up equipment and stage materials
- Availability and/or sources of spare parts for back-up equipment may be limited
- Extensive utilities may be required, such as fuel and electric for operations and support equipment
- Some methods may be limited by the volume of carcasses they can accommodate
- Some technologies may require preprocessing of carcasses and disposal of byproducts
Carcass Management: Off-Site Permitted Landfill Checklist

☐ Consult with state environmental agency for landfill advice.

☐ Access a comprehensive list of landfills using the I-WASTE Tool at go.usdatraining.com/I-WASTE.
  ☐ Log on to the I-WASTE Tool and obtain a password if you do not currently have one.
  ☐ Enter userid and password.
  ☐ Choose treatment and disposal facilities button on the lower left.
  ☐ Enter filter criteria such as “facility type (e.g., rendering, incinerators, or landfill)”
  ☐ Note that construction debris landfills are not suitable for carcass disposal, and hazardous waste landfills are not necessary unless the carcasses are contaminated with a hazardous material causing them to be classified as hazardous
  ☐ Enter State or EPA region, and click “View List of Facilities” button.

☐ Contact facilities and determine if they will accept your livestock or poultry and meet some or all of your capacity needs.
  ☐ If there is insufficient capacity, consider fast-tracking expansion of existing landfill or permitting of new landfill for this purpose.
  ☐ Consider potential environmental and biosecurity concerns.
  ☐ Verify with state environmental agency that landfill has no outstanding permit violations.
  ☐ Procure landfill services through appropriate Incident Management Team branch.

☐ If the landfill will accept the material, arrange for biosecure transport.
  ☐ Obtain controlled movement permit for transport of infected carcasses.
  ☐ Determine type of transport vehicles required. If the waste must travel on public roads, it should be transported in closed, leak-resistant trucks or dumpsters. Secondary containment may be needed, depending on the type of waste being transported. See Landfill Disposal Guidance at go.usdatraining.com/HPAI_landfill.
  ☐ Work with Depopulation Group Supervisor within the Incident Command System to determine how many animals can be depopulated per day and how many trucks will be needed for transport per day, ensuring the rates are about the same. If not, arrange for covered, leak-resistant storage.
  ☐ Pre-identify transport routes to minimize exposure to susceptible premises.

☐ If permitted landfilling is an option, see the Secure Transport and Off-Site Treatment/Burial training modules at go.usdatraining.com/Disposal and implement off-site permitted landfilling. If not, continue to Seventh Option.
BACKGROUND
Highly pathogenic avian influenza (HPAI), commonly known as bird flu, is a foreign animal disease caused by influenza A viruses. These viruses are found naturally in wild bird populations. Wild birds act as reservoirs, circulating these viruses between each other, sometimes with no clinical signs. However, HPAI can be transmitted to domestic chickens and turkeys, which may result in an outbreak. The USDA is the lead federal agency in responding to foreign animal diseases, such as HPAI.

PURPOSE
The intent of this guidance is to provide recommended waste acceptance practices for landfill disposal of HPAI infected carcasses. In an outbreak, all carcasses must be disposed of in a timely, biosecure, aesthetically acceptable, and environmentally responsible manner. Permitted landfills are an important option for disposal during an outbreak. These landfills must have necessary environmental controls to manage carcasses. In addition, strict biosecurity procedures must be followed during transportation and disposal.

PROTECTION OF LANDFILL OPERATORS
While the Centers for Disease Control and Prevention (CDC) has determined that risk for human infection from the 2014–2015 HPAI outbreak strains is low (see the CDC Interim Guidance for Landfill Workers in the United States Disposing of Poultry Carcasses During Outbreaks of HPAI), the CDC does recommend landfill operators take appropriate precautions for those involved in disposal operations. If landfills are used to dispose of carcasses during an HPAI outbreak, landfill operators should follow CDC’s guidelines, which are available in this section or by visiting go.usafraining.com/HPAI_landfill

GENERAL LANDFILLING PROCESS
All HPAI landfill operations will be supervised by personnel from USDA or State Departments of Agriculture. Contractors can be hired through the USDA to provide roll offs and other equipment at farms, CDL truck drivers (to transport roll offs to and from landfills), and personnel to perform cleaning and disinfection (C&D) of all conveyances. Contracted workers may also instruct truck drivers onsite, under the direction of landfill management.

The landfill will determine the amount of carcasses and waste materials they will accept from an infected farm. Waste materials may include manure, eggs, litter, left over feed, egg flats, pallets, used PPE, and C&D supplies. The landfill will also control the frequency of deliveries. Communication will be established between landfill management, State or federal site managers and/or case managers at an infected premises, and the USDA APHIS contracting office. Deliveries to and from the landfill are coordinated in advance between the landfill and the State or federal site manager on an infected premises.
Landfill Reimbursement

USDA APHIS may pay or reimburse landfills for operations that occur in addition to the normal course of business. This could include the following expenses, which will be negotiated at the time services are required:

- building temporary roads and entrances/exits dedicated to HPAI operations,
- purchasing additional liability insurance policies,
- hazing scavenger birds, and
- managing predators, pests, and odors related to HPAI waste disposal.

These items have been covered in the past, and will be negotiated with the landfill in advance, when farms have tested positive and emergency funding is made available. Any interested landfills should register as a federal contractor by:

All entities must register in SAM to be paid. It takes an hour or two to register and then several days for the system to update.

Producers may choose to contract directly with landfills. Producers should check with their APHIS representative regarding reimbursement at the time of an outbreak prior to any expenditures.

Guidelines for State Regulators

State Departments of Environmental Protection or Natural Resources typically determine the guidelines for containment liners, leachate management, grey water management, timelines for covering contaminated materials, the depth of covering, modifications to working faces, and permits for landfill burial. The USDA can provide suggestions and brief the landfill regulatory agencies, but ultimately it is the landfill’s responsibility to follow their State’s rules and regulations. An example of what preparations could be made in advance by State regulatory agencies can be found below.

1. Technical requirements and procedures for landfilling of HPAI wastes are established by the State-level regulatory agency responsible for permitting of landfills (State environmental agency). These requirements are designed to be protective of human health and the environment, to not jeopardize the structural or operational integrity of the landfill, and to allow the facility to operate in compliance with their land disposal facility permit. Federal/State agencies charged with protecting animal health, biosecurity, and disease control are responsible for establishing any additional technical requirements and procedures pertaining to their authorities.
2. The State environmental agency may survey all potentially qualified land disposal facilities to determine their interest in accepting HPAI wastes. Information on the technical requirements and procedures for land disposal of HPAI wastes is included in the communication so landfills can perform an initial evaluation of their facility’s capability in regards acceptance of HPAI wastes.
3. The landfill notifies the State environmental agency of its willingness to accept HPAI wastes.
4. The State environmental agency meets with landfill representatives to evaluate the suitability of their facility to accept HPAI wastes. The evaluation includes the following topics:
a. Area within the landfill for disposal of HPAI wastes; verification that the area is underlain by a leachate collection system.
b. Number of acres available for disposal of HPAI wastes.
c.Thickness of already-disposed waste layer between surface of landfill and leachate collection system.
d. Leachate management activities and method for disposal of excess leachate.
e. Logistics of HPAI waste acceptance and coordination of HPAI waste acceptance with acceptance of routine waste streams.
f. Gas collection system – location and any necessary operational changes during HPAI waste disposal activities to reduce the risk of fires.
g. Mobile incinerator – is landfill facility willing and able to host a mobile incinerator at their facility, and if so, determine if a fuel source is available.
h. Public relations and community outreach – discuss how the public and local elected officials will be informed of and educated about potential HPAI waste landfilling activities at the facility.

5. The State environmental agency informs federal/State agencies charged with protecting animal health, biosecurity, and disease control of the landfill facilities deemed technically able and willing to accept HPAI wastes for disposal.

TYPICAL EMERGENCY LANDFILLING PROCEDURES, ROLES, AND RESPONSIBILITIES

1. The landfill agrees to receive infected birds.
2. State provides permits and permit conditions to landfill.
3. USDA contractor visits the landfill to evaluate access, and works with the landfill to:
   a. plan traffic routing for trucks carrying HPAI waste,
   b. stabilize the roadway if needed,
   c. select the location for vehicle C&D, and
   d. select C&D wash water disposal option(s).
4. The USDA contractor provides recommendations for road stabilization material in addition to possible government equipment needed.
5. USDA APHIS awards contract to the landfill.
6. The landfill consults with the USDA APHIS on cost—an agreement is then made to proceed with any required modifications to handle the HPAI waste.
7. The USDA contractor sets up and operates vehicle C&D station(s).
8. The USDA contractor provides, loads, and disinfects outbound trucks at origin (e.g., sealed roll-offs lined with plastic to allow bags to slip out; biozip (or similar) bag placed in roll-off over liner; 1 foot wood chips placed in bottom of bag; birds loaded to within 1 foot of top of roll-off; biozip (or similar) bag sealed; roll-off disinfected and tarped).
9. USDA provides a permit for the truck to leave the infected premises.
10. The USDA contractor or subcontractor drives the truck to the landfill and prepares to dump where directed by landfill staff or designee.
11. The USDA contractor uses heavy equipment to open roll-off gate.
12. The truck driver tips load where directed.
13. The USDA contractor covers the waste material.
14. The landfill manages leachate in accordance with permit conditions.
15. The USDA contractor or subcontractor drives the truck to the C&D station for washing prior to leaving landfill.
16. The USDA contractor or subcontractor disposes of C&D wash water in accordance with the landfill and State requirements (likely at the municipal waste water treatment plant).
17. USDA APHIS pays the contractor and landfill when their invoices are approved.

Developed by USDA, Iowa DNR and Indiana Department of Environmental Management

◆ go.usdatraining.com/HPAI
A. Purpose and Background

The purpose of this document is to provide information and guidance for workers at landfill sites in the United States where poultry carcasses are disposed of during outbreaks of highly pathogenic avian influenza (HPAI) A(H5N2) virus. Landfill workers include mechanical equipment operators, individuals standing on the surface of the landfill when carcasses are deposited, and personnel having direct physical contact with AI virus-infected bird carcasses or potentially infected materials.

Avian Influenza (AI) Viruses

- Avian influenza (AI) viruses circulate naturally among wild birds, particularly the waterfowl reservoir, and readily enter domestic bird/poultry populations.
- Most AI viruses are low pathogenic and do not cause serious illness among infected birds or people.
- Highly pathogenic AI viruses often cause severe illness and death in infected poultry.
- AI viruses can spread quickly among birds.
- AI virus infections of people are rare, but can occur.

The HPAI H5N2 virus that caused poultry outbreaks during 2014-2015 in North America is an emerging virus. Preliminary laboratory studies indicate that this HPAI H5N2 virus is not well-adapted to humans. However, sporadic severe and fatal human respiratory illness from infections with other closely related HPAI A(H5) viruses (e.g. H5N1, H5N6) have occurred in other countries. Most human infections with avian influenza A viruses have occurred in persons not using appropriate personal protective equipment (PPE) who had exposures consisting of either 1) direct physical contact with infected birds or surfaces contaminated by the viruses; 2) being in close proximity (e.g. within 2 meters) to infected birds; or 3) visiting a live poultry market. Although no human infections with HPAI H5N2 virus have been reported to date, direct or close (e.g. within 2 meters) contact without PPE to infected birds or virus-contaminated environments may increase the risk of human infection. To reduce their risk of HPAI H5N2 virus infection, landfill workers should use appropriate PPE when disposing of poultry carcasses during outbreaks of HPAI. The following guidance, although developed for an outbreak of HPAI A(H5N2) virus, also applies to disposal of poultry carcasses during outbreaks of HPAI H5N8 and HPAI H5N1 viruses. Consultation and close coordination with public health departments are recommended.

Key points: To reduce the risk of HPAI virus infection, landfill workers should do all of the following:

Wear recommended personal protective equipment (PPE): gloves, boots, protective coveralls, goggles and a respirator) when in direct contact with infected birds, poultry carcasses, and/or poultry feces or litter;

- Avoid unprotected direct physical contact with ill birds or poultry carcasses;
- Avoid unprotected direct physical contact with bird droppings/feces from HPAI virus-infected birds;
- Wash hands with soap and water after removing gloves and other PPE. If soap and water are not readily available, alcohol-based hand rubs may be used, but must be followed by washing with soap and water once it becomes available because hand sanitizers do not reduce organic load (e.g., dirt);
• Report any illness that occurs within 10 days of the past exposure to poultry carcasses or potentially-infected materials (see section C. below for more details).

B. Guidance for landfill workers disposing of poultry carcasses

1. Bury the AI virus-infected bird carcasses and materials immediately (within 30 minutes) after unloading at the landfill.

2. Whenever possible, avoid physical handling of the carcasses by using mechanical equipment such as trucks and back hoes with enclosed cabs.

3. All landfill workers should:
   a) Use PPE including: properly-fitted safety goggles, disposable gloves, boots, a NIOSH-certified respirator (e.g., N95), and disposable fluid-resistant\(^1\) coveralls.

   (1) NIOSH-certified N95 (or higher) respirators are recommended for landfill workers who have contact with AI virus-infected carcasses or potentially infected materials.

   Respirator use should be in the context of a complete respiratory protection program in accordance with the Occupational Safety and Health Administration (OSHA) Respiratory Protection standard (29 CFR 1910.134) and other requirements. Staff that will need to wear N95 (or higher) respirators should be medically-cleared, trained, and fit-tested for respirator use. Detailed information on respiratory protection programs, including fit testing procedures, can be accessed at OSHA’s Respiratory Protection eTool: (www.osha.gov/SLTC/etools/respiratory).

   Training topics should include all of the following:

   (a) Proper fit-testing, wearing and use of respirators;

   (b) Safe removal of respirators;

   (c) Safe disposal of disposable respirators or cleaning and disinfection of reusable respirators;

   (d) Medical contraindications to respirator use.

   (2) Reusable PPE should be:

   (a) Cleaned until visible dirt is removed, and then

\(^1\) Fluid-resistant coveralls should be made of fabric that passes:
- AATCC 42 ≤ 1 g and AATCC 127 ≥ 50 cm H\(_2\)O or EN 20811 ≥ 50 cm H\(_2\)O; or
- ASTM F1670 (13.8 kPa); or
- ISO 16603 ≥ 3.5 kPA
(b) Disinfected with an EPA approved disinfectant that has label claims against influenza A viruses [http://www.epa.gov/oppad001/influenza-disinfectants.html] according to the manufacturer’s instructions.

(3) Respirator use is not necessary inside enclosed cabs when the cab’s filtration system has been independently evaluated against the NIOSH leak test method for enclosed cab filtration systems and it can be demonstrated that the cab provides the same, or higher level, of protection as an N95 respirator. The NIOSH leak test method for enclosed cab filtration systems are available on the web at [http://www.cdc.gov/niosh/mining/UserFiles/works/pdfs/2012-145.pdf](http://www.cdc.gov/niosh/mining/UserFiles/works/pdfs/2012-145.pdf).

(4) All PPE should be used in accordance with OSHA regulations found at 29 CFR 1910 Subpart I (Personal Protective Equipment). Workers should receive training on and demonstrate an understanding of when to use PPE; what PPE is necessary; how to properly put on, use, take off, properly dispose of, and maintain PPE; and the limitations of PPE.

(5) Landfill workers who may have direct contact with carcasses or potentially infected materials (e.g. individuals responsible for opening the roll-off container for unloading) should wear a disposable impermeable coverall in place of the fluid-resistant coverall referenced above or an apron over the fluid-resistant coverall to protect against exposure to liquids.

b) Safely remove PPE after burial in sequence:
   (1) Remove and dispose of the apron, if worn;
   (2) Clean and disinfect boots;
   (3) Remove boots;
   (4) Remove and dispose of the coverall;
   (5) Remove and dispose of gloves;
   (6) Wash hands with soap and water;
   (7) Remove goggles and respirator;
   (8) Clean and disinfect reusable goggles and respirator;
   (9) Wash hands with soap and water again.

c) Put on and take off PPE in separate clean areas;

d) Perform good hand hygiene such as hand-washing with soap and water or using an alcohol-based hand rub after removing PPE;

e) Avoid touching eyes, mouth, nose after touching any contaminated material while wearing PPE;

f) Do not eat, drink, smoke, or use the bathroom while wearing PPE.

---

2 Impermeable coveralls should be made of fabric and seams/closures that pass
- ASTM F1671 (13.8 kPa); or
- ISO 16604 ≥ 14 kPa
C. Reporting of illness

1. Workers at the landfill should monitor their health starting on the first day of exposure and for ten days after the last exposure to material and poultry carcasses from affected farms, and report any illness signs or symptoms (e.g. fever or feeling feverish, cough, runny nose, sore throat, headache, muscle aches, eye redness, difficulty breathing, shortness of breath, diarrhea, etc.) to the local and state public health department as soon as possible.

2. Additional information about avian influenza and worker protection can be found at:
   a) NIOSH Avian Influenza: http://www.cdc.gov/niosh/topics/avianflu/
   b) OSHA Guidance for Protecting Employees Against Avian Flu: https://www.osha.gov/dsg/guidance/avian-flu.html
   c) CDC Information on Avian Influenza: http://www.cdc.gov/flu/avianflu/
   e) CDC Prevention and Treatment of Avian Influenza A Viruses in People http://www.cdc.gov/flu/avianflu/prevention.htm
   f) CDC Interim Guidance on Influenza Antiviral Chemoprophylaxis of Persons Exposed to Birds with Avian Influenza A Viruses Associated with Severe Human Disease or with the Potential to Cause Severe Human Disease http://www.cdc.gov/flu/avianflu/guidance-exposed-persons.htm
   k) OSHA Safety and Health Information Bulletin (SHIB) on Avian Flu: https://www.osha.gov/dts/shib/shib121304.html

D. References

Planning

1. Contact state environmental agency for approval to landfill waste.

2. Identify permitted Subtitle D landfills in the vicinity of the affected premises (see EPA’s I-WASTE Tool at http://www2.ergweb.com/bdrtool/login.asp for a database of disposal facilities).

3. Contact identified landfills and ensure operator will accept catastrophic FAD mortalities, and the conditions of acceptance.

4. Verify the availability of adequate carcass storage facilities such as refrigerated rooms, transport vehicles, freezers or other means of carcass preservation.

5. Identify haulers who:
   a. Are equipped to haul carcasses in accordance with State and Federal laws.
   b. Can provide secure, leak-resistant, covered, transport for the infected carcasses and contaminated materials.
   c. Employ appropriately licensed drivers.
   d. Possess vehicles in good mechanical condition and capable of carrying the load without difficulty.
   e. Have vehicles which can be covered with a tarpaulin if they do not have closed tops.
   f. Employ drivers adequately trained in biosecurity (see 49 CFR 172 and 173 DOT regulations for further guidance).
   g. Have an emergency plan and associated supplies which address spills/excess leakage; vehicle break-downs; traffic accidents; adverse weather conditions; and terrorist attacks.

Operations

1. Don all required PPE as detailed in the Site-Specific Health and Safety/PPE Plan.

2. Prior to loading each vehicle, confirm with landfill operator(s) that they will accept the load of disease-infected carcasses. Inform landfill contact person about space, personnel, safety, and biosecurity requirements.

3. If the vehicle is not leak-resistant with a sealed cover, line the vehicle with plastic sheeting or bags and place one foot of absorbent bedding material over the liner to cushion the load and minimize the risk of puncturing the liner.

4. Puncture/vent the carcass by stabbing the area posterior to the ribs and the thoracic and abdominal cavities.

5. Load punctured carcasses into lined/leak-resistant vehicle leaving at least one foot of space at the top.

6. Seal full load.

7. Disinfect exterior of vehicle.
8. Prepare all placards and manifests in accordance with applicable regulations.
9. Obtain controlled movement permit from state.
10. Maintain a log of all shipments including
    a. the amount and type of material hauled;
    b. address of originating premises;
    c. location of landfill, contact name and contact phone number;
    d. transport vehicle license and registration numbers;
    e. driver name and contact information;
    f. supervisor’s name and signature;
    g. C&D checklist;
    h. time/date of departure from premises and arrival at disposal site;
    i. unique reference number for each load; and
    j. any unusual circumstances.
11. Transport load to the landfill, using transport routes that minimize exposure to susceptible premises.
12. Check in at weigh station.
13. Obtain receipt for weight of load and any tipping fees.
14. Proceed to working face of landfill as directed by landfill staff.
15. Have site operators open the tailgate; not the driver.
16. Tip the vehicle into the hollow under the working face or as directed by the landfill operator.
17. Landfill operators should cover carcasses immediately.
18. Proceed to designated biosecurity station to disinfect vehicle before leaving the landfill.
    See the Biosecurity and Health and Safety/PPE SOPs.
19. Properly clean and disinfect all site machinery used in the operation. See the NAHEMS Guidelines: C&D and the C&D SOP.
20. All individuals involved in the disposal process must wear appropriate PPE. See the NAHEMS Guidelines: Health and Safety, NAHEMS Guidelines: PPE, and the Health and Safety/PPE SOP.

Table 14.C-1 compares recommended actions for handling and disposing of carcasses for routine, noninfectious material and potentially infectious material.

</tbody>
</table>
In carcass rendering, whole carcasses are mechanically crushed into 2-in³ cubes of tissues, broken down thermally, and sterilized in a sealed and controllable container using pressurized steam. The process converts the carcasses into 60% water, 20% fat/tallow and 20% meat/bone meal, which is often used as animal feed. Because the rendering plant will likely be located off the affected premises, the carcasses will have to be securely transported to the rendering plant.

Planning

1. Identify carcass rendering plant(s) in the region of the affected premises; ideally one that participates in the Animal Protein Producers Industry (APPI) program to test for Salmonella in the meat and bone meal and has at least one person on site who has received training by the APPI or a certified trainer from an equivalent program. Ensure that the rendering plant has a deodorizing system. See National Renderers Association Directory.

2. Develop a memorandum of understanding with nearby counties if county lines must be crossed to reach the identified rendering plant.

3. Coordinate with the managers of the rendering plants about rendering infected carcasses. Discuss with the managers at the rendering plant:
   a. The responsible party for C&D after rendering is complete.
   b. Potential compensation for use of the facility.
   c. The volume of carcasses accepted per day.

4. Make all necessary arrangements for the transportation and delivery of carcasses to the plant, making use of the renderer’s hauling service if appropriate.

5. Ensure that all rendering plant personnel are trained on proper procedures for rendering infected carcasses, biosecurity procedures, work safety issues, and the use of PPE. If not,

6. Train the rendering plant personnel on biosecurity, work safety issues, and the use of PPE based on the Code of Practice approved October 18, 2004, by the North American Rendering Industry, as well as the Site Specific Disposal Plan, the NAHEMS Guidelines: Biosecurity, Biosecurity SOP, NAHEMS Guidelines: Health and Safety, NAHEMS Guidelines: PPE, and the Health and Safety/PPE SOP or use engineering controls to contain the system so exposures are minimized.

7. Have a Disposal Team Member available to facilitate the rendering process of disease-infected carcasses.

8. Employ biosecurity zones in the plant to minimize the risk of contamination from carcass materials entering, and of finished products exiting, the processing plant.

---

14 http://www.nationalrenderers.org/biosecurity-appi/.
9. Ensure all rendering permit conditions are met and ensure pathogens that may be emitted as aerosols from the process, particularly near the grinders are contained.

Operations

1. Don all required PPE as detailed in the Site-Specific Health and Safety/PPE Plan.
2. If possible, use the rendering company’s carcass pickup service. Regardless of the transportation provider, the transport of infected carcasses off premises must follow the transportation procedures outlined in Section 14.4.3.5.3 Transport.
3. Perform the rendering process within 24 to 48 hours of an animal’s death or as advised by rendering company.
4. Control and record the input rate relative to the size of the rendering vessel and verify that all locations in the vessel reach the minimum temperature and cooking time to inactivate the virus.
5. Properly maintain the carcass-receiving and finished-product sections as “dirty” and “clean” areas of the rendering plant and keep them separated.
6. Workers cannot move between the “dirty” and “clean” areas without personnel decontamination. See go.usdatraining.com/NAHEMS_Biosecurity and go.usdatraining.com/SOP_Biosecurity.
7. Routinely sanitize the equipment and maintain the tools used on the processing lines and in the facilities.
8. Prevent the drainage of liquids from dirty to clean areas to avoid contaminating the finished products and their transportation system.
9. Implement procedures to monitor odors and investigate and resolve odor-related complaints.
10. Monitor the cooking process.
11. Plan to dispose of the rendered products unless specifically authorized to use for pet feed. Disposal options for rendered product include composting, landfilling, or recycling at a cement kiln.
12. Thoroughly clean and disinfect all of the rendering plant equipment. See the NAHEMS Guidelines: C&D and the C&D SOP and any additional standards for returning the plant to normal production. Heating the plant to 120 F for 7 days may also be acceptable.
TRANSPORT

Transport vehicles will be needed to transport items (carcasses, other materials) to the disposal site whether it is on or off the premises. If the waste must travel on public roads, it should be transported in closed, leak-resistant trucks or dumpsters. Secondary containment may be needed, depending on the type of waste being transported. Consult a qualified waste management professional when developing this section of the plan. Some other transport planning considerations are listed below:

- Do disposal facilities selected for this premises have any special requirements for incoming waste shipments?

- Have the disposal facilities agreed to accept the type and amount of waste you plan to send them and are they permitted appropriately?

- Have members of the disposal team visited the facility to ensure it is operated in accordance with all applicable laws and regulations?

- Is there an existing contract or agreement in place with the disposal facility to receive the material?

- Are all permit, agreement, and/or contract conditions delineated and will the shipments meet the conditions? If not, what corrective actions would be needed?

- Are haulers to be used for the response properly equipped to haul carcasses in accordance with all applicable laws?

- Are transport vehicles designed to handle the materials to be transported?

- Are the drivers adequately trained in biosecurity (see 49 Code of Federal Regulations [CFR] 172 and 173 Department of Transportation [DOT] regulations for further guidance)?

- Can two-way communications be maintained with the hauler during transport?

- Do shipments require law enforcement escorts?

- What travel routes will be used from the premises to the disposal site? Consider road construction, neighborhoods, and densely populated areas, as well as susceptible farms.
Has an alternate travel route been identified?

What procedures will be followed if the vehicle is damaged during transit?

Does the receiving facility have sufficient space for incoming vehicles to avoid causing traffic disruptions on access roads? Does it have a secure location for transport vehicles, freezers, or other means of storage if there is a delay of more than 1 day?

Coordinate with State and local transportation authorities to verify any transport restrictions and obtain any necessary permit requirements and document these conditions in the site-specific plan.

How will vehicles be cleaned and disinfected before leaving the affected premises and after materials have been offloaded at the disposal site? See go.usdatraining.com/NAHEMS_Biosecurity and go.usdatraining.com/SOP_Biosecurity for more details.

How is the waste classified for transport? What DOT packaging standards apply? Are all standards consistently met, including labeling, placarding, and manifesting?

How will vehicle loading be performed in order to avoid releasing biological agent(s) to the environment?

How will transport vehicle traffic be minimized into the Control Area?
Example Rendering Plant Biosecurity Protocol

Infected materials will have temporal separation from the general rendering materials. They will be the last materials run in the plant at the end of a week. This will minimize cross contamination.

Following offloading, the trailers will be washed per incident-specific protocols and will be cleaned at a commercial truck wash prior to returning to service.

Infected material trailers will be sealed, tarped, and loaded per rendering norms or University of Minnesota Risk Assessment.

Access points between raw material processing and finished product grinding and load out will be limited to one or two hand wash/ boot wash station(s). All other access points will be sealed and no longer used. Workers will be required to clean and sanitize their hands and boots prior to entering the finished product handling area.

Developed by Texas A&M University. Source: L. Miller, personal communication, 2014
## Carcass Management: Off-Site Incineration Checklist

- Will state environmental agency approve incineration?
  - If so, see a complete list of incinerators at the EPA database at [go.usdatraining.com/I-WASTE](http://go.usdatraining.com/I-WASTE).
    - Log on to the I-WASTE Tool and obtain a password if you do not currently have one.
    - Enter userid and password.
    - Choose treatment and disposal facilities button on the lower left.
    - Enter filter criteria such as “facility type (e.g. rendering, incinerators, or landfill)”
    - Enter State or EPA region, and click “View List of Facilities” button or map facilities.

- Contact air authorities to verify operations are not in violation of their air permits.

- If the facilities are compliant, contact them and determine if they will accept your livestock or poultry and meet some or all of your capacity needs.

- If so, arrange for transport to off-site incineration facility for disposal.
  - Determine if any permits are required for transport of infected carcasses.
  - Determine type of transport vehicles required. If the waste must travel on public roads, it should be transported in closed, leak-proof trucks or dumpsters. Secondary containment may be needed, depending on the type of waste being transported. See University of Minnesota Risk Assessment.
  - Work with Depopulation Group Supervisor within the Incident Command System to determine how many animals can be depopulated per day and how many trucks will be needed for transport per day, ensuring the rates are about equal. If not, arrange for leak-resistant, covered storage.
  - Pre-identify transport routes to minimize exposure of susceptible premises.

- If off-site incineration is an option see the Secure Transport and Off-Site Treatment/Burial training modules at [go.usdatraining.com/Disposal](http://go.usdatraining.com/Disposal) and implement off-site incineration. If not, and you still need to dispose of animals, inform Operations Chief and discuss alternate strategies such as vaccination. Return to First Option and repeat cycle until all carcasses can be managed.
Planning

1. Identify permitted pathological waste incinerators in the vicinity of the affected premises (see EPA’s I-WASTE Tool at [http://www2.ergweb.com/bdrtool/login.asp](http://www2.ergweb.com/bdrtool/login.asp) for a database of disposal facilities).

2. Contact identified facilities and ensure operator will accept catastrophic FAD mortalities, and the conditions of acceptance.

3. Contact state environmental agency for approval.

4. Verify the availability of adequate carcass storage facilities such as refrigerated rooms, transport vehicles, freezers or other means of carcass preservation if storage will be needed.

4. Identify haulers who:
   a. Are equipped to haul carcasses in accordance with State and Federal laws.
   b. Can provide secure, leak resistant transport for the infected carcasses and contaminated materials.
   c. Employ appropriately licensed drivers.
   d. Possess vehicles in good mechanical condition and capable of carrying the load without difficulty.
   e. Have vehicles which can be covered with a tarpaulin if they do not have closed tops.
   f. Employ drivers adequately trained in biosecurity (see 49 CFR 172 and 173 DOT regulations for further guidance).
   g. Have an emergency plan and associated supplies which address spills/excess leakage; vehicle break-downs; traffic accidents; adverse weather conditions; terrorist attacks.

Operations

1. Don all required PPE as detailed in the Site-Specific Health and Safety/PPE Plan.

2. Prior to loading each vehicle, confirm with incinerator operator(s) that they will accept the load of infected carcasses.

3. Inform contact person about space, personnel, safety, and biosecurity requirements.

4. If the vehicle is not leak-resistant with a secure cover, line the vehicle with plastic sheeting or bags and place one foot of absorbent bedding material over the liner to cushion the load and minimize the risk of puncturing the liner.

5. Puncture/vent the carcass by stabbing the area posterior to the ribs and the thoracic and abdominal cavities.

6. Load punctured carcasses into leak-resistant or lined vehicle, leaving one foot free space at the top.

7. Securely cover load.

8. Disinfect exterior of vehicle.
9. Prepare all placards and manifests in accordance with applicable regulations.
10. Obtain permit for controlled movement from state.
11. Maintain a log of all shipments including
   a. the amount and type of material hauled;
   b. address of originating premises;
   c. location of incinerator, contact name, and contact phone number;
   d. transport vehicle license and registration numbers;
   e. driver name and contact information;
   f. supervisor’s name and signature;
   g. C&D checklist;
   h. time/date of departure from premises and arrival at disposal site;
   i. unique reference number for each load; and
   j. any unusual circumstances.
12. Transport load to the incinerator
13. Check in at weigh station if applicable.
14. Obtain receipt for weight of load and any disposal fees.
15. Proceed to unloading area as directed by facility staff.
16. Have site operators open the tailgate; not the driver.
17. The carcasses should be covered immediately and kept covered until they are moved to temporary storage or to processing.
18. Incinerate the carcasses in accordance with facility protocols.
19. Ensure the facility follows all biosecurity requirements.
20. Proceed to designated biosecurity station to disinfect vehicle before leaving the facility. See the Biosecurity and Health and Safety/PPE SOPs.
21. Properly clean and disinfect all site machinery used in the operation. See the NAHEMS Guidelines: C&D and the C&D SOP.
22. All individuals involved in the disposal process must wear appropriate PPE. See the NAHEMS Guidelines: Health and Safety, NAHEMS Guidelines: PPE, and the Health and Safety/PPE SOP.
STANDARD OPERATING PROCEDURES: 14. DISPOSAL

Attachment 14.E Air-Curtain Incineration

Planning

1. Consult with appropriate State regulatory agencies for air quality and solid-waste permits before initiating operations.
2. Inform any other local authorities about the planned thermal destruction as required.
3. Ensure that equipment, and spare parts, are available for the chosen thermal method.
4. Ensure enough trained personnel are available to maintain continuous operations.
5. Provide appropriate sustenance and housing needs for disposal personnel if necessary.
6. Assuming a mobile air-curtain incinerator will be brought to the affected premises, verify the availability of air curtain incineration units and carcass storage facilities such as refrigerated rooms, transport vehicles, freezers or other means of carcass preservation.
7. Consult with USDA NRCS and evaluate the affected premises for the depth to the water table and proper soil conditions if trench burners will be used.
8. Use refractory boxes on sites with a high water table or on rocky soil and where trenches would be difficult or costly to build.
9. Locate the mobile air-curtain unit in an area that is easily accessible to heavy vehicles hauling carcasses and equipment.
10. Gather the appropriate materials such as solid fuels (straw, hay, coal, kindling wood, untreated lumber). Base the amount of solid fuels to use on the amount of moisture in the wood or other organic sources (hay, grain, stalks, and straw) and the fat and moisture content of the carcasses. Use a fuel-to-carcass weight ratio ranging from 1:1 to 2:1. Ensure availability of enough fuel to last 2-3 days or the length of time needed to maintain uninterrupted supply.

Operations

1. Don all required PPE as detailed in the Site-Specific Health and Safety/PPE Plan.
2. Build the appropriate sized trench based on equipment vendor recommendations, or use refractory boxes. See NAHEMS Guidelines: Disposal.
3. Monitor the wind direction before and during the burning operations.
4. Keep workers out of the path of the flame.
5. Handle the ash in the refractory boxes carefully and dispose of it at a burial or land application site that has been approved by the appropriate regulatory agency.
6. If a large number of animal carcasses (exceeding a cumulative weight of 1 million pounds) require destruction, conduct the thermal destruction at a distance of 2 miles from residential buildings, roads, and utilities.
7. Use proper precautions when dealing with certain FADs such as HPAI to prevent personnel inhalation of airborne pathogens. Personnel must use proper PPE. See the NAHEMS Guidelines: Health and Safety, NAHEMS Guidelines: PPE, and disease specific Health and Safety/PPE SOPs for more information.
8. Thoroughly clean and disinfect all of the disposal equipment. See the C&D and Biosecurity SOPs.
Loading Procedures
See Secure Transport training module at go.usdatraining.com/Disposal and implement transport phase.

### PRE-LOADING

1. Complete all paperwork including manifests and/or controlled movement permits.

2. Order through ICS Logistics by 10:00 a.m. of the previous day. Specify type of delivery, type of container, size of waste, delivery time window, bin identification number, and contact name and phone number for job site.

3. Inspect and line the containers. Seal any holes or spaces with duct tape, plastic liner, caulk, or silicone. Return containers that you cannot seal.

4. Insert Biozip or similar bag.

5. Rake one foot of absorbent material on the container floor with a heavier concentration near the rear door. Close container and adjust plastic and absorbent material as needed.

6. Disinfect carcasses and/or byproducts to minimize virus spread.

**PRECAUTIONS**
- Clean and degrease work area and equipment.
- Inform driver of all activities.
- Drivers should wear PPE at all times.
- Drivers should remain seated in vehicle with windows and doors closed while truck is loaded.

Source: USDA-APHIS Secure Transport Training Module (go.usdatraining.com/transport)
LOADING

1. Load container with carcasses using a skid steer loader and/or front-end loader. Ensure carcasses are not placed on the ground while moving from the staging area to the container.

2. Load carcasses evenly. Alternate one foot of absorbent material with each layer ending with absorbent material.

3. Load is full when contents reach maximum weight limit or fill container one foot from top of container.

4. Seal Biozip bag or similar.

5. If container does not have a lid, securely fasten a tarp to the top.

6. Disinfect and inspect vehicle before departure. Verify the load is not too large, and there are no leaks, cuts, or holes. If the load is dripping, the contents must be transferred to a correctly lined container.

PRECAUTIONS

- Sheet roll-off bins on the ground.
- Use fixed ladders to enter bins.
- Use at least two people to line bins.
- Conduct heavy lifting mechanically.
- Avoid climbing the sides, backs, or onto roll-offs during inspection.
- Avoid standing or walking on top of carcasses.

Source: USDA-APHIS Secure Transport Training Module (go.usdatraining.com/transport)
POST-LOADING

1

Clean and disinfect the outside of the truck and the container. Decontamination area must be a one-way system. Animal health technicians, site managers or case managers will supervise process and issue a permit documenting proper disinfection.

2

Use pre-arranged route. No unplanned stops are permitted.

PRECAUTIONS

- Wear PPE at all times.
- Ensure drivers turn off engines prior to decontamination.
- Create a one-way system for decontamination area.
- Disinfect undercarriage, wheels, and wheel wells.
- Beware of vehicle movements, disinfectants and spread of disease.
Permit Requirements

(See Appendix IV)

<table>
<thead>
<tr>
<th>Information Required for a Permit</th>
</tr>
</thead>
<tbody>
<tr>
<td>✓ Permit Class — location, e.g., into CA, out of CA, or within CA.</td>
</tr>
<tr>
<td>✓ Permit Reason — reason for permit, e.g., direct to farm, direct to landfill, or into commerce.</td>
</tr>
<tr>
<td>✓ Origin Premises — Must be in EMRS2.</td>
</tr>
<tr>
<td>✓ Destination Premises — Must be in EMRS2.</td>
</tr>
<tr>
<td>✓ Items — What is allowed to move, e.g., manure/litter, feed, eggs, groups of animals.</td>
</tr>
<tr>
<td>✓ Item Class — Further description of item, e.g., if the item permitted was “groups of animals,” the item class offers further information.</td>
</tr>
<tr>
<td>✓ Duration/Span of Permit — First movement date, as well as how long the permit is valid for.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Additional Requirements Prior to Movement</th>
</tr>
</thead>
<tbody>
<tr>
<td>✓ Permits and their associated permitted movement may have additional requirements that must be met before the movement is made.</td>
</tr>
<tr>
<td>✓ These records and documentation can be uploaded in EMRS2 for review by relevant parties.</td>
</tr>
<tr>
<td>✓ For example, diagnostic testing or mortality reports from the premises may be required.</td>
</tr>
<tr>
<td>✓ Diagnostic testing results can be entered into EMRS2 or automatically messaged, if the testing laboratory can message results (strongly preferred), and attached to the origin premises in EMRS2.</td>
</tr>
</tbody>
</table>

Overview of the Eight Steps in Interstate Permitted Movement

**Step 1**
Unified Incident Command or Producer submits *permit request*

**Step 2**
Unified Incident Command or origin State enters/checks data in EMRS2 and accepts permit request, creating a *pending permit*

**Step 3**
Unified Incident Command or origin State reviews pending permit and documentation

**Step 4**
Origin State notifies the destination State of reviewed permit

**Step 5**
Destination State reviews and *denies permit* and notifies the origin State of their decision

**Step 6**
Destination State reviews and *approves permit* and notifies the origin State of their decision

**Step 7**
The origin State or Unified Incident Command *issues approved permit*

**Step 8**
Movement occurs

Please note: These procedures may be revised as the situation develops.

QUICK RESPONSE CARD
Ensuring responder safety is the first priority at all times.

Always know the hazards of the job, and how to protect yourself – read the SOP
Buddy system – know where your buddy is during on-farm activities
Care – take care of yourself – ppe, rest breaks, water, food, cool off
Defensive Driving – seat belts, no use of any communications devices while driving. Carry a vehicle accident kit and a first aid kit.
EAP – Employee Assistance Program – (800) 222-0364 (24 hrs/day, 7 days/week)
Fatigue – get plenty of rest and sleep – don’t drive when you’re tired
Get the Standard Operating Procedures (SOP) and understand them

Program phone numbers for your Incident Supervisor and the Safety Officer into your phone.
Make sure Location Services is enabled on your phone. Know the location of the nearest hospital.

See your Safety Officer or Incident Supervisor for more information on:
http://sp.we.aphis.gov/vs/sites/SPRS/NPIC/SiteAssets/SitePages/HPAI/Responder%20Safety%20Health%20for%20ICS%20Deployment_20May%202015%20Final.pdf (requires a VPN connection)

Heat stress
Rest breaks – take them!
Accident/injury/illness reporting
Workers Compensation (OWCP)
Check-out/check-in procedures
Respirator use
Weather
Chemical safety

Other Important Stuff

- Tell your Incident Supervisor or Safety Officer immediately if you’re injured or feel sick.
- Report hazards immediately.
- Don’t work more than 12 hours without specific supervisor instructions.
- Take breaks at least every 2 hours to cool off and drink fluids.
- If your urine is yellow, drink more water.
- Watch for weather, ticks, mosquitos, dogs, deer on the highways, hostile owners.
- Practice biosecurity: prevent contamination, clean, disinfect.
- Watch your step – booties can be slippery.
- Campylobacteriosis and Salmonellosis are among the zoonotic diseases of concern when working with poultry. Wash hands with soap after contact with animal feces. All food and water are to be consumed on the clean side of the clean/dirty line.
- Don’t enter barns during/after CO2 operations until Incident Supervisor or safety officer declares it’s safe. Stay out of foam during foaming operations.
- Shower and shampoo as soon as possible. Clean and disinfect the vehicle before leaving infected premises, and wash the vehicle after leaving the premises.
- Biosafety is very important, but don’t forget about other hazards:

Quick Response (QR) codes require a Smartphone with an enabled app – recommend “RedLaser Barcode Scanner”. Access to SharePoint also requires the Cisco AnyConnect app on your Smartphone to establish a VPN connection.

USDA HPAI website (go.usdatraining.com/HPAI)
Quick Response (QR) codes require a Smartphone with an enabled app – recommend “RedLaser Barcode Scanner”. Access to SharePoint also requires the Cisco AnyConnect app on your Smartphone to establish a VPN connection.

**BIOSECURITY**

- Electrical, machinery/vehicles, enclosed spaces/tanks/silos/pits, chemicals including disinfectants/detergents, high pressure sprayers, ammonia, walking and working surfaces.
- Wear visible ID while conducting surveillance.
- Wash hands frequently. Don’t share food or drink.
- Try to get a healthy diet. Minimize alcohol intake, especially in hot weather. Build up heat resistance over a period of several days.

**Personal Protective Equipment (PPE)**

Wear proper personal protective equipment (PPE) for the job you are doing. Don’t remove your PPE until you’re back at the clean/dirty line. Full PPE is required for work done on infected premises:

- Tyvek coveralls (Tychem coveralls for foam depopulation)
- Rubber boots or boot covers
- N95 respirators as a minimum
- Safety goggles or safety glasses with sideshields
- Gloves (double) (e.g., inner latex gloves; outer glove)
- Head bonnet and/or hardhat
- Hearing protection (disposable ear plugs) where noise is a hazard

**What to do if your PPE is breached or compromised:**

- If your PPE is breached (torn or obviously damaged), take your buddy with you and leave the work area, doff PPE, decontaminate yourself, and don new PPE. A minor tear might be “fixable” with duct tape after you’ve used alcohol gel on your skin. If your skin was cut or scraped, you should shower, then apply first aid. Let your Incident Supervisor know as soon as you can, but at least by the end of your shift.
- If you think your PPE is compromised (possibly damaged or not working properly) at any time the work being done, stop work immediately. Contact your Incident Supervisor and/or the Safety Officer for guidance. If this requires leaving the work area, take your buddy with you.

**More on the Buddy System**

While in the Hot or Exclusion Zone, use the buddy system. Work in pairs and stay in close visual contact and summon rapid assistance in case of an emergency. The responsibilities of workers using the buddy system include:

- remaining in close visual contact with their partner,
- providing their partner with assistance as needed or requested,
- observing their partner for signs of heat stress or other difficulties,
- periodically checking the integrity of partner’s PPE, and
- notifying the site manager or other site personnel if emergency assistance is needed.

All responders must follow safety and health guidelines to protect themselves and everyone around them. You risk more than your own health and safety, as well as biosecurity, if you do not.

Quick Response (QR) codes require a Smartphone with an enabled app – recommend “RedLaser Barcode Scanner”. Access to SharePoint also requires the Cisco AnyConnect app on your Smartphone to establish a VPN connection.
Personal Protective Equipment

Disposal personnel (equipment operators, drivers, contractors) will be briefed on safety requirements, site conditions, and tasks.

**IMPORTANT PPE FUNCTIONS**

- Protects user from exposure to potentially life-threatening infectious agents.
- Prevents spread of biological hazards by the user.

All personnel are responsible for understanding how to use PPE appropriately to prevent the transmission of disease.

For donning PPE and other health and safety needs, see:
- FAD site-specific health and safety plan
- NAHEMS Guidelines: Health and Safety: [go.usdatraining.com/NAHEMS_Safety](http://go.usdatraining.com/NAHEMS_Safety)
- NAHEMS Guidelines: PPE: [go.usdatraining.com/NAHEMS_PPE](http://go.usdatraining.com/NAHEMS_PPE)
- Standard Operating Procedures: Health and Safety & PPE: [go.usdatraining.com/SOP_PPE](http://go.usdatraining.com/SOP_PPE)

**PPE OPTIONS**

To reduce the risk of exposure to disease, it is important that you wear the proper PPE.

### PPE OPTIONS

Developed by Texas A&M University ([go.usdatraining.com/investigation](http://go.usdatraining.com/investigation))
PPE Requirements

**APPROPRIATE PPE**

- **EYE**: non-vented eye goggles, indirectly vented eye goggles with anti-fog coating, or alternative respirator with full face piece
- **RESPIRATORY**: N95 APR or PAPR (highly strenuous work/exposure)
- **DISPOSABLE PPE (except non-disposable items like PAPR blower/filters)**
  - Disposable latex or nitrile gloves or thick rubber gloves + chemical-resistant tape
  - Rugged impermeable boots or shoe covers that can be disinfected or discarded
  - Disposable or suitable for disinfection coveralls + impermeable apron
  - Disposable head cover, hard hat, or hood

**CLEAN UP**

- Dispose of PPE
- Disinfect boots
- Wash hands
- Shower

**PPE PROCEDURE VIDEOS**

The following videos depict proper procedures for the donning and doffing of PPE in both assisted and unassisted scenarios. To view the videos on a mobile device, scan the graphic code below with a QR code reader. The videos can also be accessed at [www.usdatraining.com/ppe](http://www.usdatraining.com/ppe)

Go-Bag Checklist

Below is a list of personal protective equipment and other biosecurity items that individuals deploying to an animal disease outbreak response may want to have upon arrival at an incident. The quantities are sufficient for 1 to 2 days unsupported by a centralized supply point.

<table>
<thead>
<tr>
<th>ITEM</th>
<th>QUANTITY</th>
<th>COMMENTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Large duffel bag</td>
<td>1</td>
<td>12 in. x 12 in. x 36 in. minimum, wheels optional. High visibility, waterproof, durable with luggage tag.</td>
</tr>
<tr>
<td>Tyvek coveralls</td>
<td>10</td>
<td>Hooded with elastic wrists and ankles. At least one per farm visit. Other coveralls made from non-woven spunbond Olefin fiber, plain or vinyl coated like Tychem, can be substituted.</td>
</tr>
<tr>
<td>Duct tape</td>
<td>1 roll</td>
<td>Keep in mind some brands of duct tape have poor adhesive qualities in cold weather.</td>
</tr>
<tr>
<td>Hard hat with ratchet</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>Head lamp flashlight with batteries</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>Respirator (N95 equivalent minimum)</td>
<td>10</td>
<td>Respirator model must correspond to fit test card.</td>
</tr>
<tr>
<td>Goggles</td>
<td></td>

Temporary vehicle wash station set-up.

Sump pump in bucket strainer.

Developed by LPMiller, USDA, 2015
PROCEDURE

1. Select a location with flat or gently sloping topography for the vehicle wash station which is between the infected zone and the exit.

2. Spread tarp on the ground.

3. Place swimming pool noodles under tarp around entire perimeter. Roll edges of tarp around noodles to promote drainage (see photo 1).

4. Place sump pump in bucket strainer on tarp at low end where water is collecting (see photo 2). Connect pump electrical cord to power outlet. Direct discharge hose to collection container or approved sanitary sewer drain (not storm sewer).

5. If using 55-gallon drums or trash cans to collect wash water, place empty containers on/in haul vehicle before filling, then pump water to container on/in truck rather than filling the container on the ground then trying to lift full container later.

6. Fill sprayers with cleaning/disinfecting solution(s). NOTE: up to 40% propylene glycol antifreeze can be mixed with water before preparing solutions if temperatures are sub-freezing.

7. Drive vehicle onto tarp.

8. Wash vehicle with cleaning solution, taking extra care on tires and wheel wells, scrubbing with scrub brushes as necessary. NOTE: tarp will be extremely slippery – use rubber overboots with good traction.

9. Use long-handled broom to push accumulating liquid towards sump pump as needed.

10. Rinse vehicle with clean water.

11. Apply disinfectant if using separate disinfection step. Ensure full wetted contact time (foam formulations are easier in this regard).

12. Rinse vehicle with clean water.

13. Drive vehicle off tarp towards exit. Do not allow vehicle to drive back into infected area prior to exiting.

14. At end of operation, wash both sides of tarp, rinse with clean water, and allow tarp to dry before storing.

15. Dispose of collected wash water in accordance with jurisdiction WRITTEN instructions. Alternately, hire properly licensed local waste hauler to remove waste water.

Developed by LPMiller, USDA, 2015
Work Zones and Control Areas

Identifying and designating work zones in the area of operations, and control areas on premises, may help prevent the transmission of the disease.

EXEMPLARY BIOSECURITY FUNCTIONS

- Protects general public and people involved
- Prevents further disease spread
- Contains the infectious agent

All personnel entering the site must:

- Meet security requirements as established by the Incident Command
- Present documentation of verified credentials showing they are qualified to perform their assigned tasks,
- Present documentation that they have received all required briefings as defined in the site-specific Incident Action Plan
- Wear the required PPE specified in the site-specific Incident Action Plan
  See Standard Operating Procedures: Health and Safety & PPE: go.usdatraining.com/SOP_PPE
- Follow all Biosecurity procedures specified in the site-specific Incident Action Plan
  See NAHEMS Guidelines: Biosecurity: go.usdatraining.com/NAHEMS_Biosecurity and
  Standard Operating Procedures: Biosecurity: go.usdatraining.com/SOP_Biosecurity

WORK ZONES

Work zones are small areas that only apply to specific premises and are identified as:

- **Exclusion Zone (EZ)/Red Zone/Hot Zone**
- **Contamination Reduction Zone (CRZ)/Yellow Zone/Warm Zone**
- **Support Zone (SZ)/Green Zone/Cold Zone**

Adapted from FADPrep Disposal Guidelines
Best Practices for Managing Contamination Reduction Zone (CRZ)

1. Set Up the CRZ
   - Set up the CRZ to allow personnel to enter/exit the zone without risk of contamination.
   - Establish a decontamination corridor for personnel/PPE.
   - Allocate a place for emergency decontamination.
   - Create a slightly sloped impervious surface that facilitates disinfectant collection, such as a plastic ground cover at least 10 x 10 meters.
   - Provide a water supply and collection system.
   - Verify that run-off water is collected or flows back into the EZ.

2. Coordinate Movement through the CRZ
   - Monitor and enforce entry and exit into the CRZ via one or two sites for authorized personnel working in the secured EZ.
   - Create four enclosed areas to allow for doffing PPE.
   - Secure all other possible entrances.

THE DECONTAMINATION CORRIDOR

Adapted from FADPrep Disposal Guidelines

Dani Ausen, Andrew Kingsbury, Iowa State University
BIOSECURITY IN THE DECONTAMINATION CORRIDOR

Area 1: PPE Cleaning & Disinfecting Area
- A washing station supplied with water and disinfectants
- Scrub or spray-off exterior protective clothing
- Thoroughly wash boots, coveralls, and gloved hands

Area 2: PPE Removal Area
- Always remove protective clothing first and discard or secure the clothing for disinfection
- Remove respirators and goggles
- Remove gloves last, by turning gloves inside out and using one gloved hand to remove the other glove
- Place clothing and equipment in prepared bins for disposal or cleaning
- Properly discard disposable items as infectious waste in accordance with all applicable regulations
- Clean/disinfect non-disposable items

Area 3: Shower Area
- Enter showering facilities if available
- Wash hair and all body surfaces
- If no showering facilities are available, proceed to dressing area

Area 4: Dressing Area
- Wash hands and face
- Change into clean clothing

CONTROL AREAS
Control areas, in comparison to the smaller work zones areas, are another means of preventing disease transmission by monitoring movement around the quarantine zone. The quarantine zone may be miles in diameter and may include many premises. For more information on control areas see the Ready Reference Guide—Zones, Areas, and Premises in an FAD Outbreak

For more information see Feed Delivery Biosecurity for Control of Disease: go.usdatraining.com/Feed_delivery

Adapted from FADPrep Disposal Guidelines
Ready Reference Guide—Overview of Zones

<table>
<thead>
<tr>
<th>Zone/Area</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Infected Zone (IZ)</td>
<td>Zone that immediately surrounds an Infected Premises.</td>
</tr>
<tr>
<td>Buffer Zone (BZ)</td>
<td>Zone that immediately surrounds an Infected Zone or a Contact Premises.</td>
</tr>
<tr>
<td>Control Area (CA)</td>
<td>Consists of an Infected Zone and a Buffer Zone.</td>
</tr>
<tr>
<td>Surveillance Zone (SZ)</td>
<td>Zone outside and along the border of a Control Area. The Surveillance Zone is part of the Free Area.</td>
</tr>
<tr>
<td>Free Area (FA)</td>
<td>Area not included in any Control Area. Includes the Surveillance Zone.</td>
</tr>
</tbody>
</table>

In the **Infected Zone** (which is **part of the Control Area**), there are movement controls and surveillance activities. Infected Premises are quarantined.

In the **Buffer Zone** (which is **part of the Control Area**), there are movement controls and surveillance activities.

In the **Surveillance Zone** (which is **part of the Free Area**), targeted poultry surveillance may be conducted (i.e. commercial premises).

In the **Free Area** (which includes the Surveillance Zone), routine or program surveillance may occur (i.e. NPIP and wild birds).
Infected, Contact, and Suspect Premises are subject to individual premises quarantines. At-Risk and Monitored Premises are subject to movement control restrictions.

### Summary of Premises Designations

<table>
<thead>
<tr>
<th>Premises</th>
<th>Definition</th>
<th>Zone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Infected Premises (IP)</td>
<td>Premises where a presumptive positive case or confirmed positive case exists based on laboratory results, compatible clinical signs, case definition, and international standards.</td>
<td>Infected Zone</td>
</tr>
<tr>
<td>Contact Premises (CP)</td>
<td>Premises with susceptible animals that may have been exposed to the FAD, either directly or indirectly, including but not limited to exposure to animals, animal products, fomites, or people from infected Premises.</td>
<td>Infected Zone, Buffer Zone</td>
</tr>
<tr>
<td>Suspect Premises (SP)</td>
<td>Premises under investigation due to the presence of susceptible animals reported to have clinical signs compatible with the FAD. This is intended to be a short-term premises designation.</td>
<td>Infected Zone, Buffer Zone, Surveillance Zone, Vaccination Zone</td>
</tr>
<tr>
<td>At-Risk Premises (ARP)</td>
<td>Premises that have susceptible animals, but none of those susceptible animals have clinical signs compatible with the FAD. Premises objectively demonstrates that it is not an Infected Premises, Contact Premises, or Suspect Premises. AtRisk Premises may seek to move susceptible animals or products within the Control Area by permit. Only AtRisk Premises are eligible to become Monitored Premises.</td>
<td>Infected Zone, Buffer Zone</td>
</tr>
<tr>
<td>Monitored Premises (MP)</td>
<td>Premises objectively demonstrates that it is not an Infected Premises, Contact Premises, or Suspect Premises. Only AtRisk Premises are eligible to become Monitored Premises. Monitored Premises meet a set of defined criteria in seeking to move susceptible animals or products out of the Control Area by permit.</td>
<td>Infected Zone, Buffer Zone</td>
</tr>
<tr>
<td>Free Premises (FP)</td>
<td>Premises outside of a Control Area and not a Contact or Suspect Premises.</td>
<td>Surveillance Zone, Free Area</td>
</tr>
<tr>
<td>Vaccinated Premises (VP)</td>
<td>Premises where emergency vaccination has been performed. This may be a secondary premises designation.</td>
<td>Containment Vaccination Zone, Protection Vaccination Zone</td>
</tr>
</tbody>
</table>

  • Transmission pathways and transmission risk  
  • Extent of animal movement  
  • Number of animals  
  • Species of animals  
  • Age of animals  
  • Movement of traffic and personnel to and from premises (fomite spread)  
  • Biosecurity measures in place at time of outbreak                                           |
| Contact Premises characteristics                                       | • Number and types of premises  
  • Susceptible animal populations and population density  
  • Animal movements  
  • Movement of traffic (fomites) and personnel to and from premises (fomite spread)  
  • Biosecurity measure in place prior to outbreak                                              |
| Environment                                                            | • Types of premises in area or region  
  • Land use in area or region  
  • Susceptible wildlife and population density  
  • Wildlife as biological or mechanical vectors                                                 |
| Climate (for aerosol spread diseases)                                   | • Prevailing winds  
  • Humidity                                                                                   |
| General area, region, or agricultural sector biosecurity               | • Biosecurity practices in place prior to outbreak  
  • Biosecurity practices implemented once outbreak detected                                    |
| Number of backyard or transitional premises                            | • Types of premises, animal movements, and network of animal and fomite movements                   |
| Continuity of business                                                 | • Continuity of business plans and processes in place or activated at beginning of outbreak (such as surveillance, negative diagnostic tests, premises biosecurity, and risk-assessments)  
  • Permit processes, memorandums of understanding, and information management systems in place or activated at beginning of outbreak |

### Minimum Sizes of Zones and Areas

<table>
<thead>
<tr>
<th>Zone or Area</th>
<th>Minimum Size and Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Infected Zone (IZ)</td>
<td>Perimeter should be at least 3 km (~1.86 miles) beyond perimeters of presumptive or confirmed Infected Premises. Will depend on disease agent and epidemiological circumstances. This zone may be redefined as the outbreak continues.</td>
</tr>
<tr>
<td>Buffer Zone (BZ)</td>
<td>Perimeter should be at least 7 km (~4.35 miles) beyond the perimeter of the Infected Zone. Width is generally not less than the minimum radius of the associated Infected Zone, but may be much larger. This zone may be redefined as the outbreak continues.</td>
</tr>
<tr>
<td>Control Area (CA)</td>
<td>Perimeter should be at least 10 km (~6.21 miles) beyond the perimeter of the closest Infected Premises. Please see the table above for factors that influence the size of the Control Area. This area may be redefined as the outbreak continues.</td>
</tr>
<tr>
<td>Surveillance Zone (SZ)</td>
<td>Width should be at least 10 km (~6.21 miles), but may be much larger.</td>
</tr>
</tbody>
</table>

For more details on zones and premises designations, please see the APHIS FAD Framework: Response Strategies (Manual 2-0): [go.usdatraining.com/FADPreP_Manual_2](http://go.usdatraining.com/FADPreP_Manual_2)

For the Secure Egg Supply Plan see [www.secureeggsupply.com](http://www.secureeggsupply.com)

### How Long Does the Process Take?

Ideally, this entire process could be completed in as soon as 60–120 days. However, the timeframe varies depending on many things (for example, flock size, depopulation and disposal methods used, test results, farm’s location). We’re committed to restoring production as fast as we can while also protecting poultry health.

### Questions?

Talk with your case manager or the State or Federal officials responding to the disease event in your area.

Source: go.usdatraining.com/HPAI_guide

For general information and contacts, visit:
Depopulation and Disposal for Birds in Your HPAI-Infected Flock

Highly pathogenic avian influenza (HPAI) is a very contagious and deadly disease for poultry. All it takes is one infected bird, and the disease can spread from flock to flock within a matter of days. As with any highly contagious animal disease, a quick and early response is our best chance to limit the size and scope of the outbreak. Depopulating affected animals is a key part of the response: it’s one of the most effective ways to stop disease spread and protect U.S. animal health as a whole.

Federal law gives the U.S. Department of Agriculture (USDA) authority to depopulate animals in these situations to stop disease spread. USDA’s goal is to complete this work within 24 hours of first detecting HPAI at a property. The sooner we act, the faster we can contain the outbreak and help business return to normal.

Your case manager will walk you through the process as we prepare to depopulate your flock and find out—as best we can—how HPAI may have entered your facility and if it has spread to any neighboring farms. We will also handle the disposal process, working with you to make sure it’s done safely, in compliance with all applicable laws, and without spreading HPAI further.

**Depopulation Methods**

There are two main methods we use to depopulate HPAI-affected flocks: water-based foam for floor-raised birds and carbon dioxide gas for caged birds. These are the most humane and effective options available in an emergency situation involving mass numbers of birds. Trained personnel will arrive onsite and handle these tasks under the supervision of Federal and State animal health officials.

If our preferred methods don’t allow us to depopulate the flock as quickly as needed—within 24 hours—we must consider other options. These may include shutting off the facility’s ventilation fans (“ventilation shutdown”). Federal and State officials will carefully evaluate your farm and work with you to figure out the best option for meeting the goal of 24-hour depopulation.

In every case, we take the decision very seriously and weigh many factors when choosing what depopulation method to use. These include, among other things, the size and type of the animals, their behavior, and their containment/housing facilities. We also look at the number of animals in the flock, the location of the farm and environmental conditions there, disease information, and available resources and personnel.

---

**WHAT IS DEPOPULATION?**

There is a difference between “depopulation” and “euthanasia.”

**Depopulation** is when large numbers of animals must be destroyed in response to an animal health emergency. With depopulation, the welfare of the animals is given as much consideration as practical, but the situation is understood to be extenuating.

**Euthanasia**, however, involves transitioning an animal to death as painlessly and stress-free as possible. While euthanasia is preferable to depopulation, it is not always possible during an animal health emergency because of the need to move quickly to slow or stop disease spread.

During an HPAI outbreak, depopulating flocks within 24 hours is crucial. It’s the best way to eliminate the disease and, overall, is a more humane approach. A lengthier depopulation process can lead to a greater number of birds suffering the terrible effects of HPAI.
USDA follows the recommendations of the American Veterinary Medical Association and the World Organization for Animal Health whenever possible. We use trained veterinarians, animal health technicians, and specialized contractors to complete depopulation work. Throughout the process, our focus is on keeping personnel safe while minimizing stress to the animals.

**Disposal Options**

There are many safe methods for carcass disposal. These include composting, onsite burial, incineration, rendering, and landfilling. Each disposal option can take a different amount of time to complete. When deciding which method to use, we look at several factors, including the size of the flock, space requirements, associated costs, local conditions, and applicable laws.

We also consider the benefits and limits to using each method:

- **Composting.** Contains the virus to the farm and produces a soil amendment/fertilizer product. However, composting requires ample flat space and may not be possible for all farming operations, such as egg layer facilities or other places where space is limited.

- **Burial.** Must be approved by the State environmental regulatory agency and may not be permitted if the water table is close to the ground surface.

- **Incineration.** A safe method for disposing of carcasses, but the fuel requirements are substantial and can be costly.

- **Rendering.** This involves processing carcasses until they are reduced to water, fat or tallow, and meat or bone meal. It is very effective but requires added safety precautions to make sure the virus does not become aerosolized and dispersed throughout the rendering plant. It is also disruptive for the plant’s normal operations.

- **Landfilling.** Landfilling allows safe and efficient disposal of large quantities of carcasses. However, individual landfill managers may put restrictions on the type or quantity of materials they accept.

Depending on the situation, we may end up taking a combined approach and use a few or all of these methods.

**For More Information**

If you have specific questions, talk with your case manager or call the nearest USDA office ([www.aphis.usda.gov/animal-health/state-offices](http://www.aphis.usda.gov/animal-health/state-offices)).

**USDA’s goal is to complete depopulation work within 24 hours of first detecting HPAI at a property. The sooner we act, the faster we can contain the outbreak and help business return to normal.**

**ACTIONS YOU NEED TO TAKE**

- Talk with your case manager about how you’ll be involved and if you’ll work directly with emergency responders on these activities.
- Wear personal protective equipment if you are on the farm at the time depopulation or disposal work is happening or if you are directly involved in this work.
- Require that your employees also wear personal protective equipment if they are on the farm or helping with response activities. Your case manager can provide guidance on personal protective equipment if needed.
- Adhere to strict biosecurity procedures at your farm.
- Follow all other steps outlined by the response team to minimize risk of spreading the disease during the process.

Source: [go.usdatraining.com/HPAI_depop](http://go.usdatraining.com/HPAI_depop)
Overview

This fact sheet identifies and describes the authorities of federal departments and agencies in support of debris operations following a presidential emergency or major disaster declaration. The following nine Federal agencies and departments are invested with authorities (described in detail below) addressing various aspects of debris management.

• Department of Homeland Security
  o Federal Emergency Management Agency
  o United States Coast Guard
• Department of Defense: U.S. Army Corps of Engineers
• Department of Agriculture
  o Natural Resources and Conservation Service
  o Farm Service Agency
  o Animal Plant and Health Inspection Service
• Department of Transportation: Federal Highway Administration
• Department of Commerce: National Oceanic and Atmospheric Administration
• Environmental Protection Agency

Department of Homeland Security

Federal Emergency Management Agency (FEMA)

• FEMA is authorized in Sections 403, 407 and 502 of the Robert T. Stafford Disaster Relief and Emergency Assistance Act to provide assistance to eligible applicants to remove debris from public and private property following a Presidential disaster declaration, when in the public interest.

• Removal must be necessary to eliminate immediate threats to lives, public health and safety; eliminate immediate threats of significant damage to improved public or private property; or ensure
the economic recovery of the affected community to the benefit of the community-at-large. The debris must be the direct result of the disaster and located in the disaster area, and the applicant must have the legal responsibility to remove the debris.

- FEMA will (1) reimburse applicants to remove eligible debris, or (2) through a mission assignment to another Federal agency (and upon request of the State) - provide direct Federal assistance when it has been demonstrated that the State and local government lack the capability to perform or contract for the requested work.

- Assistance will be cost-shared (at no less than 75% Federal and 25% non-Federal). In extreme circumstances, FEMA will provide up to 100% funding for a limited period of time.

**United States Coast Guard (USCG)**

- Under the National Contingency Plan (NCP), the USCG and Environmental Protection Agency (EPA) are responsible for providing pre-designated Federal On-Scene Coordinators (FOSCs) to conduct emergency removals of oil and hazardous materials.

- USCG is responsible for the coastal zone, and the EPA is responsible for the inland zone. The delineation between coastal and inland zones is by mutual agreement between the USCG and the EPA, and the geographic limits are indicated in Area Contingency Plans.

- Under the Comprehensive Environmental Response, Compensation, and Liability Act, or CERCLA (also known as Superfund), and the Clean Water Act, USCG has the authority to respond to actual or potential discharges of oil and actual or potential releases of hazardous substances, pollutants and contaminants that may endanger public health or the environment.

- Response actions may include containment, stabilization, decontamination, collection (e.g., orphan drums tanks and drums), and final disposal. Debris may be mixed with, or contain, oil or hazardous materials that are subject to USCG response authorities. Oil removal is funded from the Oil Spill Liability Trust Fund, while hazardous materials removal is conducted using CERCLA funds.

- USCG, under the Ports and Waterways Safety Act (33 U.S.C. §§1221), is responsible for keeping waterways safe and open. While there is no specific language stating that the USCG is responsible for debris removal from waterways, the USCG has been tasked - in the past - to assist in waterway and marine transportation system recovery.
Department of Defense

United States Army Corps of Engineers (USACE)

• USACE is authorized by Section 202 of Water Resources Development Act (WRDA) of 1976 (PL 94-587) to develop projects for the collection and removal of drift and debris from publicly maintained commercial harbors, and from land and water areas immediately adjacent thereto.

• Specific and limited local programs for continuing debris collection and disposal have been authorized (on an individual basis, with the authorized work carried out at each locality as a separate, distinct project) by Congress for:
  - New York Harbor
  - Baltimore Harbor
  - Norfolk Harbor
  - Potomac and Anacostia Rivers, in the Washington, D.C. Metropolitan area
  - San Francisco Harbor/Bay, California.

• Sections 15, 19, and 20 of the River and Harbor Act of 1899, as amended, authorize USACE to remove sunken vessels or other obstructions from navigable waterways under emergency conditions. A navigable waterway is one that has been authorized by Congress, and which USACE operates and maintains for general (including commercial and recreational) navigation. Funding for operation and maintenance of these “Federal” waterways is through USACE’s annual Operations and Maintenance General Appropriation. USACE’s policy is to oversee removal of sunken vessels by an identifiable owner, operator or lessee if the sunken vessel is in or likely to be moved into a Federal navigation channel. USACE will remove a vessel using its emergency authorities only if the owner, operator, or lessee cannot be identified or they cannot effect removal in a timely and safe manner.

• USACE is also authorized, under Flood Control and Coastal Emergencies (PL 84-99), to provide assistance for debris removal from flood control works, i.e., structures designed and constructed to have appreciable and dependable effects in preventing damage by irregular and unusual rises in water level. Under this authority, USACE requires that an applicant, to be eligible for assistance, be an active participant in its PL 84-99 Rehabilitation and Inspection Program at the time of the disaster.

Debris clean up must be for either runoff retardation or soil erosion prevention that is causing a sudden impairment in the watershed creating an imminent threat to life or property. Typically, this includes debris within channels but could also include debris in close proximity to a channel or situated where the next event could create an imminent threat to life or property. There is no size limit to the watershed except that EWP assistance is not eligible for coastal erosion restoration.

The EWP is funded through specific Congressional appropriations.

Public and private landowners are eligible for assistance but must be represented by a project sponsor (a state or political subdivision thereof, qualified Indian tribe or tribal organization, or unit of local government).

Work can be done either through Federal or local contracts. Sponsors are responsible for the 75% local cost share.

NRCS can provide assistance when the President declares an area to be a major disaster area or when an NRCS State Conservationist determines that a watershed impairment exists.

NRCS will not provide funding for activities undertaken by a sponsor prior to the signing of an agreement between NRCS and the sponsor.

**Farm Service Agency (FSA)**

Emergency Conservation Program (ECP) is authorized by Sections 401 - 406 of the Agricultural Credit Act of 1978, PL 95–334, and provides emergency assistance for debris removal from privately-owned land following a natural disaster. It is funded through Congressional supplemental appropriations.
• The damage must be so costly that Federal assistance is or will be required to return the land to productive agricultural use or to provide emergency water for livestock.

• The ECP provides emergency cost share funding (up to 75% federal share) and technical assistance for farmers and ranchers to remove debris (other than animal carcasses).

**Animal, Plant and Health Inspection Service (APHIS)**

• APHIS has two programs under which it can provide debris removal assistance:
  - Veterinary Services (VS) program authorized by Animal Health Protection Act (7 U.S.C. 8301–8317) which provides for removal and burial of diseased animal carcasses.
  - Plant Protection and Quarantine (PPQ) program authorized by Plant Protection Act (Title IV, Pub. L. 106–224, 114 Stat. 438, 7 U.S.C. 7701–7772). This program manages issues related to the health of plant resources. Primary objective is to regulate and monitor in order to reduce the risk of introduction and spread of invasive species, including planning, surveillance, quick detection, containment, and eradication.

• Both public and private lands are eligible under these programs which provide assistance to Federal, State, tribes, local jurisdictions, and private landowners to manage animal and plant health by collecting and providing information, conducting or supporting treatments, providing technical assistance for planning and program implementation (removal).

**Environmental Protection Agency (EPA)**

• EPA’s primary authorities related to debris removal fall into two categories: (1) authorities related to cleaning up debris that is mixed with or contains oil or hazardous materials; and (2) authorities related to establishing standards for proper management of debris (hazardous and non-hazardous). EPA generally does not remove non-hazardous debris after emergencies/disasters.

• Under the Comprehensive Environmental Response, Compensation, and Liability Act, or CERCLA (also known as Superfund), and the Clean Water Act, EPA and the United States Coast Guard (USCG) have the authority to respond to actual or potential discharges of oil and actual or potential discharges of hazardous substances, and to actual or potential discharges of pollutants and contaminants that may present an imminent and substantial danger to the public health or welfare.
EPA has responsibility for responses in the inland zone and USCG has responsibility for responses in the coastal zone. The delineation between the inland and coastal zone is determined by mutual agreement by the EPA and USCG, and the geographic boundaries are indicated in Area Contingency Plans.

EPA and USCG carry out these responsibilities under implementing regulations known as the National Oil and Hazardous Substances Pollution Contingency Plan (NCP). EPA and USCG pre-designate Federal On-Scene Coordinators (FOSCs) to direct and coordinate response actions.

Response actions may include containment, stabilization, decontamination, collection (e.g., orphan tanks and drums), and disposal. Debris may be mixed with, or contain, oil or hazardous materials that are subject to these response authorities.

CERCLA requires that the State in which the site is located fund 10% of remedial action costs, with the other 90% drawn from the Superfund. However, where the potentially responsible party is a political subdivision of a State, the State must agree to fund 50% of the remedial action costs, with the other 50% drawn from the Superfund.

The Resource Conservation and Recovery Act established a framework for Federal, State, and local cooperation in controlling the management of hazardous and non-hazardous solid waste. The EPA role is to establish minimum regulatory standards that are, in most cases, implemented by the States and to provide technical assistance. EPA administers other laws as well that may impact the management of debris (e.g., Clean Air Act requirements that apply to asbestos-containing debris). Again, some of these programs may be delegated to the States.

FEMA may mission assign the EPA through the United States Army Corps of Engineers to dispose of household hazardous waste following a major disaster declaration from the President.

**Department of Transportation**

**Federal Highway Administration (FHWA)**

The Emergency Relief (or ER) program is authorized in Title 23, United States Code, Section 125, from the Highway Trust Fund, and supports repair or reconstruction of Federal-aid highways and roads on Federal lands which have suffered serious damage as a result of natural disasters or catastrophic failures from an external cause.

Debris removal from Federal-aid roads is eligible for 100% reimbursement during the first 180 days following an emergency event that qualifies and is approved for the ER program.
DEBRIS REMOVAL
AUTHORITIES OF FEDERAL AGENCIES

- The ER program is funded $100 million in annual authorizations. If the annual authorization is expended, FHWA will reimburse eligible costs when ER funds become available.

- The State must incur a cost of at least $700,000 statewide to qualify for ER assistance. The cost of individual projects (sites) must be $5,000.

- It is the responsibility of individual States to request ER funds for assistance in the cost of necessary repair of Federal-aid highways damaged by natural disasters or catastrophic failures.

Department of Commerce

National Oceanic and Atmospheric Administration (NOAA)

- NOAA’s Office of Coastal Survey is responsible for surveying and charting the nation’s waters and coast, and has been heavily involved in hydro-surveying using side-scan and multi-beam sonar to identify hazards and debris and dangers to navigation along the Gulf Coast for the last three years.

David Garratt
Acting Director of Recovery
Federal Emergency Management Agency

1/27/07
Date
As part of its safeguarding mission, the U.S. Department of Agriculture’s (USDA) Animal and Plant Health Inspection Service (APHIS) coordinates the National Veterinary Stockpile (NVS) program.

The NVS is our Nation’s repository of veterinary “countermeasures”—animal vaccines, antivirals, supplies, equipment, and response support services. Simply put, it exists to provide States, tribes, and territories with the tools they need to combat an animal disease outbreak. In an animal health emergency, the response must be fast and well coordinated to keep disease from spreading. The NVS can dispatch—within 24 hours—critical resources animal health officials need onsite.
With NVS support, officials can set up immediate measures to contain and eradicate the disease, minimizing the animal losses and other economic damages that result from an outbreak. In addition to providing resources and materials when outbreaks occur, NVS personnel help States, tribes, and territories prepare for future outbreaks through careful advance planning, training, and exercises. Our goal is to make sure that, when faced with an emergency, our partners understand the process for rapidly requesting, receiving, processing, and distributing NVS resources so responders get help quickly.

Training and Exercises

We help States, tribes, and territories plan for potential disease outbreaks to support a smooth response should they need NVS resources. For example, we offer a planning guide, a plan template, and other tools that explain in detail what logistical factors to consider when preparing for an agricultural emergency. Our staff can also share their first-hand experiences and expertise in handling various disease situations, which further aids the planning process.

Once a plan is in place, our staff conduct logistical training and exercises with NVS partners per the Homeland Security Exercise Evaluation Program. These exercises give participants an opportunity to:

- learn in detail about the NVS program and available resources;
- test their abilities to request, receive, process, and distribute NVS equipment, supplies, and vaccines;
- clarify roles and responsibilities to aid in a logistics operation; and
- identify resource gaps and improve response plans before outbreaks occur.

What We Offer

Equipment and Supplies

The NVS offers many resources to address animal health threats during disease outbreaks. These resources (i.e., veterinary countermeasures) include:

1) personal protective equipment for on-the-ground responders to guard against infection and other onsite hazards;
2) decontamination supplies to inactivate pathogens;
3) vaccines to quickly protect livestock and poultry at risk of infection;
4) vaccination equipment and supplies (such as needles and syringes) to effectively immunize large numbers of livestock and poultry;
5) animal handling equipment, including corrals, to safely contain and restrain livestock;
6) equipment for emergency euthanasia and depopulation of animals;
7) assistance in securing outside companies, if needed, to provide trained personnel and additional equipment for large-scale depopulation, disposal, and decontamination work.

Contact Us

To learn more, visit our Web site at http://nvs.aphis.usda.gov or email us at nvs@aphis.usda.gov.

You can also reach our staff by phone at (301) 851-3595 or fax at (301) 734-7817.

In an emergency, please call our 24/7 hotline: 1-800-940-6524.

USDA is an equal opportunity provider and employer.

Issued June 2013
Questions and Answers: The National Veterinary Stockpile and the 24 Hour Push Pack

The National Veterinary Stockpile (NVS) program, coordinated by the U.S. Department of Agriculture’s (USDA) Animal and Plant Health Inspection Service (APHIS), provides support to States, Tribes, and Territories responding to damaging animal disease outbreaks. Within 24 hours, the NVS can provide veterinary countermeasures—including certain types of animal vaccines, antivirals, supplies, equipment, and response services—to animal health officials in affected areas. To learn more about this program, see the NVS factsheet go.usdatraining.com/NVS_factsheet.

One of the services NVS provides is shipping the “24 Hour Push Pack” when needed to combat a damaging animal disease outbreak.

Q. What is a “24 Hour Push Pack?”
A. A 24 Hour Push Pack is the initial shipment of supplies. The shipment will arrive within 24 hours of APHIS’ approval to deploy resources. The requestor only needs to provide basic information about the situation, and we will coordinate the transport of supplies needed to respond to a damaging animal disease.

There are four details we need to determine which push pack is most appropriate for the situation:

1) **Type of disease**—this helps determine whether a standard or high-protection push pack is needed. High-protection push packs include high-level respiratory protection, such as Powered Air Purifying Respirators (PAPR).

2) **Number of responders expected**—this determines the number of push packs needed. Each push pack supports 10 responders for 10 days, changing 6 times per day. When making your request, round the number of responders up to the nearest multiple of 10.

3) **Incident command point-of-contact** to coordinate the NVS deployment

4) **The physical address of the facility** that will receive NVS supplies

Once we receive this information, the NVS Deployment Management Team will determine what to provide immediately.

Q. What does a push pack contain?
A. Depending on the level of protection needed, there are two types of push packs.

A standard protection push pack contains four modules:
- 2 Tyvek personal protective equipment (PPE) modules, which include 450 PPE kits, a first aid kit, bulk nitrile gloves, and boot covers;
- 1 Tychem module, which includes 150 PPE kits; and
- 1 decontamination module, which contains disposable aprons, isolation bags, Ziploc® bags, long-handled brushes, buckets with covers, pop-up ultra pols, shoe and boot scrapers, EMS shears, 2-gallon sprayers, chemical tape, caution tape, and Virkon® S test strips.

An emergency vaccination request can also include a module containing vaccine ancillary supplies (e.g., needles, syringes, and sharps containers). In the event of a foot-and-mouth disease (FMD) outbreak, you may request a second vaccine ancillary supplies module containing pink FMD tags. This request is subject to North American FMD Vaccine Bank (NAFMDVB) approval; NVS stores the pink FMD tags for the NAFMDVB.

A high-protection push pack contains five modules:
- 2 Tyvek PPE modules, which include 450 PPE kits, a first aid kit, bulk nitrile gloves, and boot covers;
- 1 Tychem module, which includes 150 PPE kits;
- 1 decontamination module, which contains disposable aprons, isolation bags, Ziploc bags, long-handled brushes, buckets with covers, pop-up ultra pols, shoe and boot scrapers, EMS shears, 2-gallon sprayers, chemical tape, caution tape, and Virkon S test strips; and
- 1 PAPR module, which contains the 3M™ Breathe Easy™ PAPR System.

If emergency vaccination is approved, you may also request a module containing vaccine ancillary supplies (e.g., needles, syringes, and sharps containers). In the event of a foot-and-mouth disease (FMD) outbreak, you may request a second vaccine ancillary supplies module containing pink FMD tags. This request is subject to North American FMD Vaccine Bank (NAFMDVB) approval; NVS stores the pink FMD tags for the NAFMDVB.

Source: The National Veterinary Stockpile and the 24 Hour Push Pack (go.usdatraining.com/NVS_pushpack)
Q. What sizes of PPE are included in each 24 Hour Push Pack?
A. Each PPE module contains 2XL and 3XL suits. The NVS staff determined, after careful consideration, that these two sizes fit the vast majority of responders.

Q. Will all of the 24 Hour Push Packs arrive on one truck?
A. NVS can typically load 50 to 52 modules in one tractor trailer. This equates to 10 push packs, with the remaining 2 spaces available for possible vaccine ancillary supplies. If you require more than 10 push packs, expect more than one tractor trailer.

Q. Do the 24 Hour Push Packs arrive on pallets?
A. The push packs are fully contained in Tri-Walls™, which consist of triple-walled, fiberboard sleeves, a plastic top, and a plastic bottom pallet. The sleeve can be locked with the bottom pallet and top to form a rigid and secure system that eliminates the requirement for banding, stretch wrap, or strapping material. They are 40 inches by 48 inches and are either 45 inches or 52 inches tall. The plastic top and bottom pallet can be removed and the sleeve folded for storage. Forklifts or pallet jacks move them easily.

Q. How are the 24 Hour Push Packs configured? How can I quickly identify items in the pack?
A. Each 24 Hour Push Pack consists of modules that are packed with like items. This allows warehouse personnel to quickly find specific items; for example, all decontamination supplies are packed in modules that have been labeled with a number “4.” We also attach a detailed packing list to the outside of each module that identifies the contents. A packing diagram for each module is included on a drop flap.

To expedite filling requests, the NVS uses the following color-coded labeling system to distinguish the contents of each module so that items can be located quickly:

- Blue = PPE
- White = decontamination supplies
- Yellow = vaccines, antivirals, and vaccination supplies
- Green = PAPR systems

Q. Can empty modules be used to ship supplies from a storage location to a premises?
A. Empty Tri-Walls must be returned to an NVS logistics center so that they can be reused. The NVS Deployment Management Team will arrange for pickup and transport back to one of our centers.

Q. If I have questions about the NVS, who should I contact?
A. Email us at nvs@aphis.usda.gov with any questions. More information is also available on our Web site go.usdatraining.com/NVS

Questions and Answers: The National Veterinary Stockpile and 3D Response Support Services

The National Veterinary Stockpile (NVS) program, coordinated by the U.S. Department of Agriculture’s (USDA) Animal and Plant Health Inspection Service (APHIS), provides support to States, Tribes, and Territories responding to damaging animal disease outbreaks. Within 24 hours, the NVS can provide veterinary countermeasures—including certain types of animal vaccines, antivirals, supplies, equipment, and response services—to animal health officials in affected areas. To learn more about this program, see the NVS factsheet go.usdatraining.com/NVS_factsheet

NVS provides depopulation, disposal, and decontamination (3D) response support through a variety of contractors.

Q. What are 3D response support services?
A. “3D” refers to depopulation, disposal, and decontamination activities. These activities commonly require the rapid deployment of large numbers of response personnel and equipment. The NVS maintains contracts with all-hazards emergency response companies to assist with 3D operations as needed and serves as the single point-of-contact within APHIS for 3D response support services.

Q. What types of services can 3D contractors provide?
A. 3D response support services include:

- surge personnel fully equipped with personal protective equipment;
- decontamination equipment and mobile teams to support field responders onsite;
- waste management and disposal, including carcass and debris recovery, handling, and disposal;
- hazardous and infectious material transportation and access to landfills;
- staging area setup and operations for distribution of equipment and materials;
- certified operators for special equipment, including forklifts, skid loaders, and heavy trucks/equipment; and
- special equipment such as mobile command centers, emergency power and lighting, pumps/pressure washers, and satellite terminal and radio communications.

Q. How experienced are the 3D contractors in responding to agricultural emergencies?
A. All of our 3D contractors receive annual training from NVS specific to agricultural emergency response. We design this training to ensure that our contractors are proficient—and efficient—in responding to these types of emergencies and in using NVS equipment and resources. Our contractors also participate in the NVS exercise program, which reinforces lessons learned and prepares them on an operational level for responding to agricultural emergencies.

The 3D contractors are also highly trained in all-hazards emergency response and are capable of deploying with their own equipment and supplies. They are experts in decontamination and disposal operations, including State requirements for transporting and disposing of hazardous materials. The contractors operate within the National Incident Management System.

Q. How quickly will 3D contractors arrive onsite? What is their surge capacity?
A. The 3D contractors will arrive within 24 hours of receiving the approval to deploy and report to Incident Command. Depending on services required, the contractors can deploy approximately 600 personnel within 72 hours and 1,000 personnel within a week.

Q. What happens if there are simultaneous events and multiple requests for 3D services?
A. We work with multiple 3D contractors to ensure redundancy in coverage.

It is a common business practice in the all-hazards emergency response industry for companies to work together to get the job done. For example, during...
the first days of the 2010 Deepwater Horizon oil spill, NVS conducted an unannounced notification exercise with our 3D contractors while conducting a full-scale deployment exercise with one of the 3D companies in attendance. All 3D contractors indicated they had the capability to respond to an agricultural emergency while responding to the oil spill at the same time.

Q. How do I request 3D services during an animal disease event?
A. Call our 24/7 emergency hotline at 1-800-940-6524.

Q. If I have questions about NVS or 3D services, who should I contact?
A. Email us at nvs@aphis.usda.gov with any questions. More information is also available on go.usdatraining.com/NVS

USDA is an equal opportunity provider and employer.
USDA Avian Influenza Response: Mass Depopulation and Carcass Disposal

As part of its safeguarding mission, the U.S. Department of Agriculture (USDA) protects the health of the Nation’s livestock and poultry. USDA responds to major animal disease events, helping to keep dangerous diseases from spreading and threatening even more animals. USDA also works to reduce the economic impact of disease events.

Since December 2014, USDA has confirmed cases of highly pathogenic avian influenza (HPAI) H5 in the Pacific, Central, and Mississippi flyways (or migratory bird paths). The disease has been found in wild birds, as well as in a few backyard and commercial poultry flocks. The Centers for Disease Control and Prevention (CDC) considers the risk to people from these HPAI H5 infections to be low. No human cases of these HPAI H5 viruses have been detected in the United States, Canada, or internationally.

In responding to the detections, USDA must depopulate affected flocks to prevent the spread of this highly contagious disease to additional flocks and must safely dispose of all depopulated birds. USDA and State officials evaluate disposal options based on the size of the flock, local conditions, and applicable laws/regulations.

Mass Depopulation Method

- HPAI eradication activities typically involve quarantine and movement controls, a humane depopulation component, disposal, and cleaning and disinfection activities.
- When depopulation is deemed necessary, Federal authorities, in conjunction with State and Tribal agricultural officials and industry, will euthanize infected birds and affected flocks.
- USDA’s Animal and Plant Health Inspection Service (APHIS) employs depopulation technologies that are humane, limit human exposure to the AI virus, and better accommodate large-scale eradication efforts.
- The use of water-based foam has the potential to reduce the number of workers involved in depopulation efforts, decreases their exposure to zoonotic HPAI viruses, is relatively easy to deploy under field conditions, and will mitigate the physical threat to responders who depopulate animals in a structurally unsound building.
Biosecurity During Carcass Disposal

If USDA determines that moving the carcasses to a landfill for disposal is the best available option, animal health officials will ensure this move is safe for both landfill operators and the general public, and that all necessary biosecurity steps are followed.

General Carcass Disposal

Q. What are the carcass disposal options?
A. There are a variety of safe methods for carcass disposal. These methods include composting, onsite burial, incineration, rendering, and landfilling.

Q. How do animal health officials decide which disposal method to use?
A. USDA and its State partners evaluate disposal methods based on a variety of factors, including the size of the flock, space requirements, associated costs, local conditions, and applicable laws/regulations. There are benefits and limitations to using each method:

- **Composting.** This method contains the virus to the farm and produces a soil amendment/fertilizer product. However, composting requires wide-open spaces and may not be feasible for all farming operations, such as egg layer facilities or other facilities where space is limited.
- **Burial.** On-farm carcass burial must be approved by the State environmental regulatory agency and may not be permitted if the water table is close to the ground surface.
- **Incineration.** Incineration is another method that can be safely used to dispose of carcasses. The limitation of this method is that the fuel requirements are substantial and can be costly.
- **Rendering.** This involves processing carcasses until they are reduced to water, fat or tallow, and meat or bone meal. It is very effective but requires additional safety precautions to ensure that the virus does not become aerosolized during the rendering process and transported throughout the plant. It also necessitates disruption of the plant’s normal operations.
- **Landfilling.** Landfilling allows safe and efficient disposal of large quantities of carcasses.

When necessary, USDA takes an integrated approach and uses a combination of some or all of these methods.

Landfilling—Health and Safety Concerns

Q. Is landfilling an environmentally safe option for HPAI carcass disposal?
A. Yes. Landfills are highly regulated by the U.S. Environmental Protection Agency (EPA) and—in many cases—individual States to ensure that disposed materials do not present a risk to human health and the environment. Under EPA and State regulations, landfills are located, designed, operated, and monitored to ensure protection of the environment from contaminants that might be present.

Source: USDA Avian Influenza Response: Mass Depopulation and Carcass Disposal (go.usdatraining.com/depopulation)
Q. What measures are in place at the landfill to protect the environment?
A. There are numerous, overlapping safety controls in place to protect the environment. For example, per EPA and State requirements, municipal solid waste landfills must include an impermeable liner overlaying 2 feet of clay soil along the bottom and sides of the landfill. This protects groundwater and soil from water that trickles through the landfill and absorbs some of its materials, referred to as leachate. In addition, a collection and removal system sits on top of the liner system and removes leachate from the landfill for treatment and disposal.

Q. Will the carcasses in the landfill pose a threat to human health?
A. No. The CDC considers the risk to people from these HPAI H5 infections to be low. No human cases of these HPAI H5 viruses have been detected in the United States, Canada, or internationally. In addition, the virus does not survive more than 6 days in carcasses held at room temperature.

Carcass Transport

Q. How will the carcasses be safely moved to the landfill?
A. A clean trailer is brought onsite by State-licensed haulers and is fitted with a biosecure containment bag. The carcasses are then loaded into the biosecure containment bag, which is sealed, and the truck and trailer—including the exterior of the biosecure containment bag—are disinfected with EPA-registered products labeled for this use. Upon arrival at the landfill, the biosecure containment bag slides out and is immediately buried. The truck and trailer are then cleaned and disinfected again prior to leaving the landfill.

Q. Will moving the carcasses spread the virus to new locations or farms?
A. No. USDA has conducted a thorough assessment of the risks associated with transporting such carcasses; the risk assessment found that, when transporting the carcasses is necessary, the movement can be done safely and will not spread the disease if the protocols described are followed. In addition, we employ several layers of redundant safety measures and carefully monitor all cleanup and disposal activities to ensure that they are done in compliance with USDA protocols.

Q. Who is ultimately responsible for ensuring this transport is done safely?
A. USDA is responsible for ensuring that carcasses are transported safely. Each truck carrying infected carcasses is issued a permit by USDA which allows it to move outside of the quarantine zone. USDA also establishes the requirements that must be met to allow such movement.

Q. Has this been done successfully in previous disease outbreaks?
A. Yes. USDA has successfully used landfilling in several major disease situations over the years. In 2002, USDA used landfills to dispose of turkeys infected with low pathogenic avian influenza in Virginia and routinely uses landfilling in Wisconsin to dispose of cervid carcasses infected with chronic wasting disease.

Source: USDA Avian Influenza Response: Mass Depopulation and Carcass Disposal (go.usdatraining.com/depopulation)
Q. Is there anything the public or producers in the area need to do?
A. All bird owners, whether commercial producers or backyard enthusiasts, need to continue:

- practicing good biosecurity,
- preventing contact between their birds and wild birds, and
- reporting sick birds or unusual bird deaths to State/Federal officials, either through your State veterinarian or through USDA’s toll-free number at 1-866-536-7593.

You can find more information online at http://healthybirds.aphis.usda.gov.

USDA is an equal opportunity provider and employer.
FY2016 HPAI Response
Timeline, Eligibility, and Approval for Restocking

March 30, 2016

Please note: These procedures may be revised as the situation develops.

DOCUMENT HISTORY & RELATED DOCUMENTS

This document updates and supersedes the following documents:

- Timeline to Restocking & Environmental Sampling Procedures
- Restocking Criteria for Previously Infected Premises.

Please also see the following, related policy documents (www.aphis.usda.gov/fadprep):

- Protocol for Environmental Sample Collection and Testing for Al Virus
- Cleaning & Disinfection Basics (Virus Elimination).

INTENDED USE

This document provides guidance to State Animal Health Officials (SAHOs), USDA Animal and Plant Health Inspection Service (APHIS) Officials, and Incident Management Teams (IMTs) for the restocking of highly pathogenic avian influenza (HPAI)-infected commercial poultry premises. This includes the timeline to restocking and criteria that must be met for premises to restock.

In order for premises to restock after HPAI infection, they must meet the minimum time requirements, all criteria laid out in this document, AND be approved to restock. Being approved to restock indicates that in addition to finishing all the steps in the restocking process, the premises has met any additional criteria that may have been laid out by the State or APHIS, and that State and APHIS officials have agreed in writing that the premises can be restocked.

BIOSECURITY MEASURES

All biosecurity practices currently in place on the premises (including use of personal protective equipment [PPE]) will be followed for activities discussed in this document, including sample collection for environmental testing and final inspection of the premises prior to quarantine release. The level of PPE needed for different activities (environmental sampling, for example) will be determined by the SAHOs and/or IMTs.

TIMELINE TO RESTOCKING OF PREVIOUSLY INFECTED PREMISES

The timelines provided below offer guidance on just the steps, time, and sampling it takes to reach the point to be eligible to begin the restocking process and, ultimately, approved to restock.

Timelines for Restocking for Premises Using Composting

Please see Figures 1 through 3 for the timelines on premises using composting. Figure 1 covers in-house composting, Figure 2 covers outdoor composting, and Figure 3 covers the combination of in-house/outdoor composting.

For premises using composting, environmental sampling inside the houses/barns occurs after the compost pile is complete and removed from inside the barns. For outdoor composting, environmental sampling inside the houses/barns can occur after the houses/barns are cleaned and disinfected.

Source: Timeline, Eligibility, and Approval for Restocking (go.usdatraining.com/criteriarestock)
Please note: There is no requirement OR option to release compost based upon compost sample testing.

Figure 1. Timeline for Disposal & Premises Restocking:
IN-HOUSE COMPOSTING

Figure 2. Timeline for Disposal & Premises Restocking:
OUTDOOR COMPOSTING

Source: Timeline, Eligibility, and Approval for Restocking (go.usdatraining.com/criteriarestock)
Figure 3. Timeline for Disposal & Premises Restocking: COMBO OF IN-HOUSE/OUTDOOR COMPOSTING

Timeline for Restocking for Premises Using Burial

For premises using burial, environmental sampling is performed inside the houses/barns after the premises is cleaned and disinfected following disposal. Figure 4 provides the restocking timeline for premises using burial.

Figure 4. Timeline for Disposal & Premises Restocking: BURIAL

Source: Timeline, Eligibility, and Approval for Restocking (go.usdatraining.com/criteriarestock)
RESTOCKING PREVIOUSLY INFECTED PREMISES

A primary goal of the HPAI response is to ensure that the response efforts and activities do not cause more damage and disruption than the disease outbreak itself. However, restocked premises that subsequently become infected with HPAI a second time place added stress on already strained resources and continue the risk of ongoing HPAI transmission in commercial poultry. As such, APHIS urges appropriate caution restocking premises in an HPAI outbreak.

Restocking Assessments

Two assessments must occur to restock previously infected premises:

1. An assessment of the previously Infected Premises being restocked. This includes the environmental sampling results and assessment of whether the premises has met the timeline requirements in Figures 1-4 (as applicable to the specific premises).

2. An assessment of the surrounding area or Control Area in which the Infected Premises is located. Assessment information includes the epidemiological curve (rate of new infected premises), geospatial risk factors, and other epidemiological risk factors for the previously infected premises.

Indemnity

APHIS will not indemnify previously Infected Premises that are restocked without written APHIS and State approval and subsequently become an Infected Premises a second time. For premises that meet the following criteria, including written approval by APHIS and State officials that restocking can occur, full indemnification will be provided by APHIS as funds are available.

Restocking Process

When a premises finishes virus elimination, and a final inspection of the premises has been completed, the premises enters the restocking phase of the response. At this point, the premises can begin the restocking process (in other words, the premises is “eligible to begin the restocking process/pending restock approval”), but is not yet approved to restock.

In order to restock a previously Infected Premises, all of the following criteria must be met:

1. The owner and/or grower meets, for the original Infected Premises, the requirements of the
   a. State Quarantine Notice or Hold Order(s); AND
   b. USDA Flock Plan.

2. An assessment that the premises meets the minimum conditions laid out in this document with regard to timeline to restocking, including the
   a. Minimum fallow time, for the method of disposal chosen; AND
   b. Environmental sampling, with no evidence of HPAI infection.

3. In consultation with State animal health officials, the owner evaluates risk factors at the start of the 21 day fallow period (that begins upon completion of virus elimination activities).

When these three steps have been completed, the premises can then seek approval to restock from APHIS and State officials. To restate: a premises may only seek approval to restock when the premises is 21-days post completion of final virus elimination, environmental sampling is complete and shows no evidence of HPAI, and the premises meets requirements of the State Quarantine Notice/Hold Order and the USDA Flock Plan.

Source: Timeline, Eligibility, and Approval for Restocking (go.usdatraining.com/criteriarestock)
Approval for Restocking

After all of the above criteria are met in the “Restocking Process” section, premises become ready for State and APHIS officials to approve the restocking. Additional criteria, particularly further biosecurity measures, may be required by State and/or APHIS officials in order for the premises to be restocked; State requirements may vary by State:

1. The owner and/or grower will complete any additional surveillance, biosecurity procedures, and requirements for movement as may be required by the State and APHIS upon and following restocking. These biosecurity requirements may include, but are not limited to, the following areas:
   a. Cleaning and disinfection procedures for all movement onto the farm and all movement into and between barns.
   b. Personnel-specific biosecurity measures, including barn specific clothing not to be worn outside.
   c. Exclusion of wild birds and rodents from the barn structure.
   d. Measures to ensure feed and water are not contaminated by wild birds or their feces.
   e. Immediate mitigation of standing water, feed spills, and other environmental factors that may attract wild birds.
   f. Elimination of visits by non-essential personnel.

After State/APHIS criteria have been met and State and APHIS officials have assessed the Control Area, they will approve, in writing, that the premises can be restocked. The premises is now “approved to restock.” This means that the premises has met all the requirements set by State and APHIS officials to be approved to restock, and has a signed restock agreement. In some cases, the formal Restock Approval Letter may be issued a few days prior to the end of the fallow period; however, the premises cannot restock until the date on the Letter. Any USDA Flock Plan requirements pertaining to restocking remain in place.

Premises that are Eligible but Not Approved for Restocking

At times, a premises may have completed the 21-day fallow period and have negative environmental testing, but not be approved to restock because of ongoing disease cases in the Control Area. These premises are “eligible to begin the restocking process/pending restock approval” until State and APHIS officials assess the Control Area and determine that a Restock Approval Letter can be issued to the premises. At this point the premises is “approved to restock.”

Premises that Do Not Plan to Restock

There may be the case in which a premises does not plan to restock immediately or in the near future and therefore does not seek a Restock Approval Letter (but may complete the rest of the steps outlined above). These premises will continue to be “Pending Restock Approval” until State and/or APHIS officials approve, in writing, that the premises can be restocked. The steps in the “Restocking Process” section must be documented in EMRS in the same manner regardless of the premises’ intention to obtain a Restock Approval Letter from State/APHIS officials.

Testing for Restocked Birds

Birds used for restocking must be from flocks tested for HPAI. These flocks must be tested for HPAI prior to movement; the minimum standard is 2 negative rRT-PCR tests at least 24 hours apart, with one negative test within 24 hours of movement.

**EXECUTIVE SUMMARY OF THE METHOD**

Composting is a biological heating process that results in the natural degradation of organic resources (such as poultry carcasses) by microorganisms. Composting has been successfully used throughout the United States for nearly two decades to control outbreaks of low pathogenicity avian influenza (LPAI) and highly pathogenic avian influenza (HPAI). Composting can be effective with most bird types and poultry house designs.

Microbial activity within a well-constructed compost pile can generate and maintain temperatures sufficient to inactivate the avian influenza virus. The effectiveness of this virus inactivation process can be assessed by evaluating compost temperatures and the shape of the time and temperature curve, visual observation of carcass decomposition, and the homogeneity of the compost mix.

**Successful mortality composting requires the following:**

1. A qualified composting expert to guide windrow construction.
2. Trained equipment operators.
3. Sufficient carbon, water, and space.

**If any of these components is lacking, composting is NOT recommended.**

KEY ELEMENTS FOR SUCCESSFUL COMPOSTING

The role of the Subject Matter Expert (SME) is to ensure that these key elements are followed in the construction of compost windrows:

1. Windrows (typically 6 to 8 feet high and 12 to 15 feet wide) are constructed on an adequate and uniform base layer (10 to 15 inches thick) of a sufficiently porous and absorbent carbon material.

2. The base layer and windrow are not compacted with equipment.

3. Good carcass to carbon contact is ensured by creating a core with a minimum 1:1 mix, by volume, of carcasses, carbon, and other infected material (manure, egg shells, feed, etc.). DO NOT GRIND/CRUSH/MACERATE THE CARCASSES DURING CONSTRUCTION!

4. Windrows should be constructed to ensure adequate distribution of moisture throughout; the windrows are capped with carbon material (8 to 12 inches thick) to ensure that no carcasses are exposed and to minimize odor.

5. Windrow dimensions, including the base and cap, may be reduced for smaller carcasses.

LABOR, EQUIPMENT, AND SUPPLIES

- Skilled equipment operators and general laborers;
- skid loader(s), pay loaders, dump trucks, rakes, and scoops;
- sawdust, litter, wood shavings, corn stover, active compost, seed and nut hulls, woodchips, or other carbon material; and
- compost thermometers (36” or 48” stem length).

PROTOCOL

Prior to Windrow Construction

- Evaluate barn configuration to determine if space is adequate for windrow(s) construction within the poultry barns. If not, assess other on-site structures or outside compost sites.
  - To assess outside sites, see Appendix A.
- Evaluate type and quantity of infected materials to be composted:
  - Carcass: type, size, number and condition
  - In-barn manure/litter: volume, moisture content, density
Mortality Composting Protocol for Avian Influenza Infected Flocks

- Stored manure/litter: volume, moisture content, density
- Feed: quantity, location
  - Empty feed from feed bins and pans, distribute evenly into the mix.
- Eggs: quantity and condition
- Clean bedding
- Paper products
- Non-infected manure compost.

➤ Calculate the amount of carbon needed for composting:
  - See Appendix B for calculations.
  - The characteristics of various materials are listed in Appendix I.

➤ Evaluate premise for supplemental water:
  - Source
  - Application method.

➤ Evaluate on-farm equipment and determine supplemental equipment needs.

➤ Ensure all overhead lines and poultry house equipment are removed or out of the way. Secure any loose cords, cables or hoses so that they will not become entangled by equipment.

➤ Minimize ventilation to reduce the risk of disease transmission while balancing air quality for worker safety.

➤ Transfer all infected on-site materials into compost windrows.

Typical Windrow Construction Protocol

Three critical elements of windrow construction are: 1) a porous base layer, 2) a uniformly mixed windrow core, and 3) an adequate cap (see Figure 1). These steps may be done concurrently or as separate steps.

Figure 1. Cross Section of Compost Windrow

![Figure 1. Cross Section of Compost Windrow](image-url)
Windrow Base Construction

- Before in-house composting, clear carcasses and litter from the windrow location(s) of the poultry house to create a 12–15 foot wide work area for construction of the windrow base(s). Distribute the material from on either side of the pathway. (See Appendix C for in-house variations.)

- Before outside composting, an adequate site must be identified (see Appendix A). Site modifications and approval from State and local agencies may be required.

- Using the largest loader possible, begin building the windrow base.

- The windrow base should be 12–15 feet wide with a depth of 10 to 15 inches. (Note: base will compress over time.)
  - Carbon material for the base should be porous and bulky enough to allow adequate air flow into and through the windrow. Ideal materials for the base include bark mulch or coarse wood chips. Other acceptable materials include: straw, wood shavings, active compost, small grain hulls, and corn stover. Also, coarse woody material in excess of 2 inches in size should be avoided to ensure that the resulting compost can be land applied as a soil amendment.
  - If these materials are not available, poultry litter may be used for the windrow base if it is sufficiently dry, porous, and bulky.
  - To maintain the base’s porosity and to avoid compaction, do not drive equipment on the base.

Construction of the Core

- The windrow core should consist of a uniform mix of carcasses and litter. The easiest way to get a uniform mix throughout the windrow is to scoop litter and birds together in each bucket load and add it to the windrow in a manner that thoroughly mixes the contents of the bucket. If additional carbon material is needed, the material should support heat generation (i.e., composting). Suitable materials include fresh wood shavings, active compost, poultry litter, straw, corn stover, and small grain hulls. In many instances this material may need to be blended with the existing litter and carcasses to be suitable.
Any remaining feed should be blended and mixed with the carcasses and litter before windrow construction. Be sure to move infected material as little as possible.

The mix of carcasses and litter should be added from both sides of the windrow. This allows the operators to reach the center of the windrow and avoid compacting the base with the tires or tracks of the loader.

The windrow core should be constructed such that 1 foot of base material is exposed on both sides of the windrow.

Add water as needed.

The core should be dome-shaped and of sufficient height to include the litter and carcass mix from the area adjacent to the windrow. At this stage, the windrow height should not exceed 6 feet.

Continue building the core until all of the litter and carcasses have been placed on the base.

An alternate method of using pre-compost windrows is described in Appendix C.

**Capping the Windrow**

Prior to capping the windrow, remove any carcasses that are near the edge of the windrow base and include them in the core of the windrow.

Cap the windrow with 8 to 12 inches of a suitable carbon material. Carbon material for the cap should prevent flies from contacting carcasses, serve as an insulating blanket, and allow air to flow out of the piles. This material may be finer in texture than the base. Suitable material includes small grain hulls, sawdust, new bedding, and wood chips. Straw, corn fodder, or similar material may also be suitable; however, experience has shown that these products can blow off the windrow and may need to be thicker to serve this purpose than other materials.

Ensure that the entire core is uniformly covered with cap material with no carcasses exposed.

Avoid compacting the windrow. Do not operate the loader’s tires or tracks onto the sides of the windrow while capping.

The completed windrow should be approximately 6 to 8 feet high.

Windrows should be numbered and flagged by the SME at a minimum of 10 temperature monitoring locations spaced equidistantly the length of each windrow.
Layering Method

As an alternative to the core construction method described previously, the windrow core can be constructed by layering carcasses and carbon material. Base and cap construction is the same as in the standard protocol. Following base construction, proceed in the following manner:

- Add a 12–15 inch layer of litter and birds, then cover with a 12–15 inch layer of wood chips or other carbon source.
- Add another layer of litter and birds until the windrow is two or three layers high and as long as needed.
- Cover the windrow with an 8–12 inch layer of wood chips or other carbon sources. The finished pile should be 6 to 8 feet high.

The SME may choose to use either or both of these construction techniques depending on site conditions.

Approval of Windrow Design

SMEs should evaluate the windrows to ensure that they have been constructed consistently with this protocol. Approval will be documented on the Compost Approval Checklist in Appendix G.

Temperature Monitoring

Once the windrow construction has been approved by the SME, daily temperature monitoring can begin following the standard temperature monitoring SOP found in Appendix D. Temperature data should be collected on the temperature log included in Appendix E or in a comparable electronic document. The health and safety of the individual conducting the temperature monitoring should be protected by following the ammonia safety procedures outlined in Appendix F.
**Turning the Windrows**

After the State Animal Health Official (SAHO), APHIS Official, Incident Management Team (IMT) Official, or SME has provided their approval based on windrow design and an evaluation of the temperature data collected during the initial 14-day compost cycle (Phase 1), the windrow is eligible for turning. Approval will be documented on the Compost Approval Checklist in Appendix G. No turning is allowed before the end of the 14-day period. Turning needs to provide for the homogenization of the core, base, and cap materials. Windrows need to maintain adequate porosity and structure after turning. If soft tissue is observed on the windrow surface, a 2 to 4 inch carbonaceous cap should be applied. See Appendix H for turning equipment and methods.

**Release of the Compost**

After the SAHO, APHIS Official, IMT Official, or SME has provided their approval based on windrow design and an evaluation of the temperature data collected during the second 14-day compost cycle (Phase 2), the compost may be moved without restriction on the premises or may leave the premises with appropriate permits. Approval will be documented on the Compost Approval Checklist in Appendix G.

**Composting Egg-Layer Manure and Waste Feed**

During an HPAI outbreak, there may be a need to compost layer manure and waste feed. This may be because the producer has chosen to dispose of their poultry mortalities by a method other than composting—such as on site burial, incineration, or landfilling—or because there was more manure on the farm than could be practically composted with the poultry carcasses. In general, the compost process used for these materials is identical to the windrow construction process described above. However, because of the density of the manure and feed, it is imperative that the material be thoroughly blended with carbonaceous materials to help ensure proper porosity within the windrows. Generally, manure can be composted with a 1:1 mix of manure and carbonaceous material. Often, layer manure has a high moisture content or is extremely dry depending on manure management, and the moisture content of the windrows may need to be adjusted.
TRoubleshooting

The table below describes some of the most common composting problems and possible solutions.

<table>
<thead>
<tr>
<th>Problem</th>
<th>Issue</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Excessive flies or odor</td>
<td>Exposed carcasses</td>
<td>Add additional cap material</td>

APPENDIX A
SITING A COMPOST LOCATION FOR DISPOSAL OF POULTRY CARCASSES

Selection and siting of environmentally suitable and appropriate locations for composting of poultry carcasses infected with avian influenza is an important consideration in the disease management process. Because of the virulent nature of this disease, it is important to locate such sites within or in close proximity to the infected premises. The site access should be able to handle heavy truck traffic and allow for biosecurity around the site’s perimeter, securing access to and from the site. Additionally, due to the relative putrescibility of the carcasses and associated litter, it is critical to choose sites that will not be adversely impacted by potential releases of nutrient-laden leachate nor will result in nuisance complaints in the event that odors, flies, or scavengers begin to appear on-site.

In general, emergency poultry mortality compost sites should be large enough to accommodate all of the generated carcasses, litter, waste feed, and other contaminated materials, as well as have the ability to store any additional amendment materials that may be needed for successful composting. Along with the criteria noted above, ideal HPAI compost sites should

- be located such that the prevailing wind directions do not travel to nearby residences (whenever possible),
- be located at the top of the slope of the field, on moderately-well to well drained soils (usually land that is used for crop production),
- have a gentle 2%–4% slope to encourage on-site drainage,
- contain on-site soil depths in excess of 24 inches to seasonal high water tables,
- contain on-site soil depths in excess of 36 inches to bedrock,
not be located on a flood plain,
be constructed or designated for the current emergency,
have (or construct) diversion ditches, terraces, or berms to direct surface water flows and storm water away from active compost piles. (Note that if piles are located between production houses, then roof and surface drainage should be directed away from the compost area), and
the edges of the identified site should have these following minimum setbacks, including:
   – 200 feet from a water supply well used for drinking;
   – 200 feet from water bodies, including: ponds, lakes, streams, rivers;
   – 200 feet from a nearby residence (not owned by the premises);
   – 50 feet from a drainage swale that leads to a water body (see above); and
   – 25 feet from a drainage swale that does not lead to a water body.
APPENDIX B

METHODS OF ESTIMATING CARBON (BULKING AGENT) NEEDS

Methodology

Described below are three approaches to estimating the amount of additional carbonaceous materials needed to compost poultry carcasses. All three require estimating the volume of litter in a building. To do this:

1. Obtain the length and width of the building.
2. Estimate the average depth of existing litter.
3. Calculate cubic feet of existing litter = length (in feet) × width (in feet) × depth (in inches) /12.
5. Modify the estimate based on the condition of litter (volume should be reduced if there is a large volume of 'cake' or of very wet litter).

Once an estimate of the existing litter has been made, an estimate of the total amount of carbonaceous material is needed. Below are three approaches for estimating the total.

Method 1. Weight Based Estimate

a. Effective in-house composting must have a minimum of 1.5 pounds of carbon material (based on bulk density of 30 pounds/cubic foot material) per pound of bird, (1 pound of carbon per pound of bird for the base and cover and the remaining carbon for the mix).

b. Determine total pounds of birds
   i. Pounds of birds = number of birds × average weight in pounds.

c. Determine total pounds carbon needed
   i. Total carbon = pounds of birds (from above) × 1.5.

d. Determine pounds of litter in house
   i. Cubic feet of litter in house (see above)
   ii. Pounds of litter = cubic feet of litter × weight of a cubic foot of litter (Average bulk density = 30 pounds; Range = 25 to 35 pounds).

e. Determine amount of additional carbon needed
   i. Cubic yards of additional carbon needed = ((total pounds of carbon needed-pounds of litter in house)/(weight per cubic feet of carbon material))/(27)
      1. wood chips, litter or wet sawdust = 30 pounds/cubic foot
      2. dry sawdust = 15 pounds/cubic foot.
Method 2. Volume Based Estimate
a. Assume bulk density of litter is 30 pounds/cubic foot or approximately 800 pounds/cubic yard. This means the following:
   i. Each 20 pound bird requires 30 pounds or 1 cubic foot of carbon material
   ii. Each 40 pound bird requires 60 pound or 2 cubic feet of carbon material.
b. To calculate total carbon material needs, perform the following calculations:
   i. Multiply number of 20 pound birds by 1 to get cubic feet then divide by 27 for cubic yards.
   ii. Multiply number of 40 pound birds by 2 to get cubic feet then divide by 27 for cubic yards.
c. To estimate additional volume needed, subtract the total volume of litter in the building (see above) from the total volume of carbon material required.

Method 3. Computerized Estimator
a. First, use the Spartan Emergency Animal Tissue Composting Planner v1.03 to estimate the total amount of amendment needed.
b. Then use the Spartan Compost Recipe Optimizer v1.04 to estimate the amounts/proportions of amendments needed; given the availability of amendments (poultry manure, poultry litter, sawdust, bark, etc.).
c. Go to this site: http://msue.anr.msu.edu/program/info/managing_animal_mortalities and then select “Composting Tools.”
APPENDIX C
VARIATIONS ON TYPICAL WINDROW CONSTRUCTION PROTOCOL

Variations Based on House Design

The three critical elements of a porous base layer, a uniformly mixed windrow core, and an adequate cap, must be maintained for successful virus inactivation regardless of variations in house design, bird size, or available carbon material.

Pole Supported Houses

► Although the support poles may limit the maneuverability of the loaders, the windrow construction protocol remains the same.
► Avoid constructing windrows against wooden support poles.
► Additional time will be required to construct windrows in this type of house due to space and structural constraints.
► Depending on the width of the house and the pole configuration, two windrows may need to be constructed instead of a single windrow in the center of the house.
► Due to structural constraints and limited maneuverability, experienced and skilled loader operators are required to minimize damage to the building and equipment.
Turkey Breeder Houses

- Although designs of turkey breeder houses may vary, generally the nests and other equipment can be moved to the center and sides of the house to make space for the construction of two windrows.

- Because of limited operating space, windrows may need to be shorter (5 feet tall) and narrower (10 feet wide). This will allow the loader operator to construct the windrow core and place the cap from one side of the windrow.

- Eggs and feed should be evenly distributed onto the core of the windrow.

- Eggs should be broken with the loader bucket to facilitate decomposition and inactivation of virus.

Breeder Turkey Toms

- Breeder toms can weigh between 60 and 80 pounds.

- Due to their size, more carbon material may be required to maintain good carcass to carbon contact.

- Handling and placing the carcasses in the windrow may be difficult due to their size and the tendency of the carcasses to roll to the edge of the windrow. Additional labor may be necessary to appropriately position the carcasses on the windrow.

- Additional capping material may be needed to ensure that all carcasses are adequately covered.

Broiler-Breeder Houses with a Center Scratch Area

- Slats and nests need to be moved outside the house after depopulation.

- Carcasses and litter in scratch area should be scooped up with a loader(s) and dumped onto the middle of the manure which was under the slats. Place equal amount of carcasses on both manure piles.

- Dump any feed onto the manure.

- Bring in carbon material to build a base 10 inches deep and 12 foot wide in the scratch area. Ensure that the base does not touch the wooden slat supports.
Using the loader(s), mix the carcasses, manure and feed, and place this core mix on the base, maintaining 8 to 10 inches around the edge of the base. Work from both sides as you progress down the house making sure there is enough core mix placed on the base to evenly distribute the material the length of the house.

Using the loader(s), place 8 to 10 inches of woodchips or bark mulch on top of the core mix, making sure that this cap does not touch the wooden slat support and that all carcasses are covered.

Broiler-Breeder Houses with Scratch Areas on the Sides
- The manure from under the center slats will be placed on the carcasses in the side scratch areas.
- Follow same procedure as above for building the windrow in the area under the center slats.

Variation of the Standard Core Construction Technique

Pre-Compost Windrows
An alternative construction method, which increases the amount of carbon material mixed within the windrow core, is to form 2 pre-compost windrows, cap, and then form 1 final windrow. This is especially useful when dealing with large amounts of carcass material relative to litter, creating a significant C:N imbalance, or when additional carbon material will increase porosity. Forming pre-compost windrows also stabilizes the tissue and begins a heating process until a single windrow can be constructed.

- Remove litter and carcasses along sidewalls and the center of the house, forming 2 pre-compost windrows extending the length of the house.
- Cap each windrow with 8–12 inches of suitable carbon material.

Pre-compost windrows (photo by Josh Payne)
In the center of the house, construct a 12–15 feet wide base that is 10–15 inches deep.

Combine both capped windrows onto the base, mixing litter, carcasses, and added carbon material.

Cap the final windrow with 8–12 inches of suitable carbon material.

APPENDIX D
TEMPERATURE MONITORING PROCEDURE

Monitor temperatures of the windrow daily at a minimum of 10 locations flagged by the SME. The temperature monitoring locations should be spaced equidistantly the length of each windrow. Take two temperature readings at each flagged location within a foot of the flag; one reading at a depth of 18 inches and another reading at a depth of 36 inches. To ensure consistent temperature monitoring to the same depth, mark the thermometer probe at 18 inches and 36 inches. Place the temperature probe ¾ of the way up the windrow at a 45 degree angle. Ideally, temperatures should be monitored by a single individual for consistency. Temperature probes should be calibrated before use.

Instructions

Turn on fans or open the doors and curtains to all the houses containing compost piles to allow them to air out and to maximize ventilation.

USE THE BUDDY SYSTEM. Entering a barn with active compost or dead birds requires a two person team.

Place the stem of the thermometer approximately 18 inches and then 36 inches into the compost pile half way up the pile at a 45 degree angle.

Leave the thermometer at each depth and point for at least 60 seconds.
Log the reading from the thermometer from each flag and at both depths.

Compare readings to previous day's readings.

After completing the house readings, close the doors and curtains.

Calculate the average temperature for each pile by averaging both depths and note it on the Composting Temperature Log.

Windrows should reach an average temperature of 131 °F for a minimum of 72 hours at both the 18 inch and 36 inch depths or be assessed by a SME for possible corrective measures.

Disinfect the thermometer and return it to its protective case.

Each thermometer will be kept at the respective premises being monitored. Do not take a thermometer from one premise to another.

If 3 days after initial windrow construction, compost temperature averages are consistently (more than 3 days) below 100 °F or greater than 160 °F, a SME should be consulted immediately.

During Phase 2, a SME should be consulted immediately if any monitoring location is consistently (more than 3 days) below 100 °F or greater than 160 °F.

APPENDIX F
IN-HOUSE COMPOSTING AMMONIA SAFETY

Background

Ammonia is produced naturally from decomposition of organic matter, including plants, animals and animal wastes and can become concentrated in enclosed structures. This guidance is for ammonia produced from these natural sources, NOT from compressed gas cylinders or other sources which may produce very high air concentrations.

Signs of Exposure to Ammonia

Strong odor provides adequate early warning of its presence, but prolonged exposure can be hard to detect due to olfactory fatigue and adaptation. High concentrations can cause airway destruction resulting in respiratory distress or failure. Signs of exposure include the following:

› burning of the nose, throat and respiratory tract;
› coughing; and
› skin and eye irritation.

How to Reduce Ammonia Exposure

› Increase ventilation when possible.
› Reduce the amount of time spent in areas where levels of ammonia are high.
› Wear proper PPE (personal protective equipment)
   – gloves,
   – half face with goggles or a full face respirator with at least a particulate/ammonia cartridge (green) or a multigas cartridge, and
   – cloth coveralls or disposable coveralls (Tyvek).
› If possible, measure levels of ammonia in work area with an air gas meter before entering, or know recommended exposure times based on the ammonia levels in work area.

Phase 1 Recommendations of State Animal Health, APHIS or IMT Official:

☐ I have observed the windrows at this site and in my professional judgment they have been constructed consistent with the criteria outlined in the Mortality Composting Protocol for Avian Influenza Infected Flocks. Additionally, windrow temperatures have reached the average temperature of 131 °F for a minimum of 72 hours. The 14-day initial composting cycle is complete.
Mortality Composting Protocol for Avian Influenza Infected Flocks

☐ I have observed the windrows at this site and in my professional judgment they have NOT been constructed consistent with the criteria outlined in the Mortality Composting Protocol for Avian Influenza Infected Flocks. The windrows should be evaluated by a composting Subject Matter Expert to recommend corrective actions if necessary.

☐ Windrow temperatures have NOT reached the average temperature of 131 °F for a minimum of 72 hours. The windrows should be evaluated by a composting Subject Matter Expert to recommend corrective actions if necessary.

APPENDIX H
WINDROW TURNING EQUIPMENT AND METHODS

Windrow turning should occur at 14 days after the windrow construction is completed. There are several methods for turning windrows, both for in-house and outside windrows. The windrows constructed in-house may be turned inside the house or moved outside and reformed.

Methods for Turning Windrows In-House

1. Use skid loaders or telehandlers with high-capacity buckets to turn windrows. Starting at the end of the windrow, scoop up all compost, turn machine around and drop the mixture forming a new windrow. It needs to be dumped in a manner that provides maximum aeration.

Turning in-house with a skid loader (photo by Josh Payne)

2. Use small dozer to roll over windrows.
   a. Requires a skilled operator to avoid damaging equipment and building.
   b. Requires building the original windrow off center to allow space to turn the pile.
   c. Only feasible in larger houses.

Methods for Turning Windrows Outside

1. Use large articulated loader(s).
   a. Skid loaders have too small a bucket for this method (too slow and they don’t mix the material as well).

2. Use dozer to roll over windrow.
   a. Does not mix material as well as other methods.

3. Use tractor attached mechanical compost turner.
   a. Thoroughly mixes and shreds material but may be slower than using large loaders or straddle type windrow turners.
b. Requires 2 passes for larger windrows.

4. Straddle-type windrow turner (tractor pulled).
   a. Windrows should be constructed far enough apart to allow the tractor and turner to operate (width of tractor approximately 10 to 12 feet).
   b. Mixes material well.
   c. Need a large unit to turn 12–15 foot windrows (at least 14 foot wide)—the “toe” of the windrows can be removed by a loader to reduce the width of larger windrows.

Landfills and Highly Pathogenic Avian Influenza (HPAI) Response

May 2016
USDA APHIS Veterinary Services
“Worst agricultural disaster in decades”

Why does it matter?

• Financial impact of HPAI
  • US, Regional, State economies
  • $960+ million spent on response since December 2014
  • International trade: several countries banned poultry from the United States
    • Billions in lost exports
    • Direct/indirect impacts-jobs, affiliated industries, emotional impact

• Safe food supply (perception)
  • Safe to eat meat, eggs

• Potential public health issues
  • NOT currently infectious to humans, virus can change
DEFINITIONS

• USDA APHIS Veterinary Services
  • US Department of Agriculture, Animal and Plant Health Inspection Service
  • Veterinary Services oversees pre-harvest animal production
• FAD: foreign animal disease
• HPAI: highly pathogenic avian influenza
  • Also referred to as “high path AI”
  • Differentiated from low pathogenic AI based on morbidity and mortality, or how quickly birds get sick and/or die from the disease
  • Current high path strain in U.S. is mainly H5
• FMD: foot and mouth disease
• PPE: personal protective equipment
• Zoonotic Disease: a disease that can be spread from animals to humans
• Depopulation: also known as “culling” or “stamping out” a large number of animals to quickly eliminate the disease
HOW ARE DISEASE OUTBREAKS HANDLED?

• Is it a disease of high consequence?
  • e.g., High Path Avian Influenza, Foot and Mouth Disease, African Swine Fever, Rift Valley Fever, Glanders

• What is the scope of the outbreak?
  • County, State, Regional, National
  • Can that jurisdiction respond without national assistance (funding, equipment, people)?

• Is it a zoonotic disease?
  • Will humans become infected?

• Who would be the lead agency?
  • Animal Diseases: State Departments of Agriculture, USDA APHIS Veterinary Services
  • Human Diseases: Center for Disease Control and Prevention (U.S. Department of Heath and Human Services), State Public Health Departments
WHAT ARE THE GOALS IN A FAD OUTBREAK?

In the event of an FAD outbreak, the three key response goals are:

1) Detect, control, and contain the outbreak as quickly as possible.

2) Eradicate the FAD using strategies that stabilize animal agriculture, the food supply, the economy, and protect public health and the environment.

3) Provide science- and risk-based approaches and systems to facilitate continuity of business for non-infected animals and non-contaminated animal products.

Achieving these three goals will allow individual livestock facilities, States, Tribes, regions, and industries to resume normal production as quickly as possible. They will also allow the United States to regain FAD-free status.
USDA Poultry Production Data
May 2015

The most recent Census of Agriculture reported 233,770 poultry farms in the United States in 2012.

In 2014, the U.S. poultry industry produced:
- 8.54 billion broilers,
- 99.8 billion eggs, and
- 238 million turkeys.

The combined value of production from broilers, eggs, turkeys, and the value of sales from chickens in 2014 was $48.3 billion, up 9 percent from $44.4 billion in 2013.
Today’s Commercial Industry

- 8.5 billion meat chickens
- 150 million meat turkeys
- 250 million table egg layers
- 88 million meat type chicken breeders
- 4.5 million egg type chicken breeders
- 8 million breeder turkeys
- 253 meat type chicken hatcheries
- 35 turkey hatcheries
Figure 1. Broiler Production by State Number Produced, Thousand, 2012

Lesser known poultry industries: game birds, backyard birds, and hobby birds of any species
How did we get here?
2014-2015 and 2016 HPAI Outbreaks
Update on Avian Influenza Findings
Poultry Findings Confirmed by USDA’s National Veterinary Services Laboratories

232
Detections Reported

6/17/2015
Last Reported Detection (IA)

12/19/2014
First Detection Reported

49.6 Million
Number of all birds affected
2014-2015 HPAI Outbreak in the United States

• First case detected in Oregon, December 2014
• Total number of HPAI positive premises: 232
  • 211 commercial (MN-109, IA-72, WI-9, SD-10, NE-5, CA-2, MO-2, ND-2, AR-1)
  • 21 backyard
• Commercial poultry depopulated
  • Turkeys: approx. 7.5 million
  • Chickens, laying hens and pullets: approx. 42.1 million
Impact

• Approximately 10% of the poultry meat and egg supply was destroyed in 6 months in 2015.

• Food prices increased.

• Virus prefers cold, damp weather, so it “slowed down” during the hot summer months (last confirmed positive in Iowa mid-June, 2015).

• Birds that commingle up north will fly south for the winter, potentially exposing wild, commercial, and backyard birds to the virus.
Trade Implications from the 2014-2015 HPAI Outbreak

- Trade impact
  - 18 countries imposed bans on ALL U.S. poultry and products
  - 38 countries imposed partial or regional bans

Trade bans on U.S. exports of broiler and turkey meat related to HPAI as of June 16, 2015 (data from USDA ERS)
2016 HPAI Outbreak

• First case detected January 16, 2016 in Dubois County, Indiana:
  • One case of HPAI in commercial turkeys
  • Nine cases of LPAI in commercial turkeys
    • Strain similar to that seen in wild birds in North America
  • 415,000 birds euthanized
  • Economic cost: over $20 million.
Does HPAI pose a health threat to humans?

• To date, there have been no human cases related to this H5 strain of HPAI (nearly 4300 responders nationwide).

• The Centers for Disease Control and Prevention (CDC) considers the risk to people from these H5/H7 infections to be low. No humans cases of these H5/H7 viruses have been detected in the United States, Canada, or internationally.

• Historically, human infections with other avian influenza viruses have occurred after close and prolonged contact with infected birds or the excretions/secretions of infected birds (e.g., droppings, oral fluids), as in SE Asia.
What happens once a farm is infected?

Highly Pathogenic Avian Influenza
A Guide To Help You Understand the Response Process

1. Detect
   You see unusual signs of illness or sudden deaths in your flock. You report it to your private or state veterinarian. Samples are taken and tested. You find out your flock is positive for HPAI.

2. Quarantine
   USDA and State personnel come to your farm. We assign you a caseworker who will be your main point of contact onsite, answer your questions, and guide you through the needed paperwork. We will also place your operation under quarantine, meaning only authorized workers are allowed in and out; and movement restrictions for poultry, poultry products, and equipment go into effect. We contact neighboring poultry farms and start testing their birds to see if they’ve been affected, too.

3. Appraise
   We work with you to create a flock inventory. This list shows you how many birds you have, what species they are, their age, and other key details that will help us give you 90 percent of fair market value for your birds.

4. Depopulate
   Infected flocks are depopulated as quickly as possible—ideally within 24 hours of the first HPAI detection—so that no virus is left on the farm.

5. Compensate
   You receive your first indemnity payment quickly in the response process. We also pay you a standard amount for virus elimination activities (cleanup work).

6. Manage Disposal
   USDA will help you dispose of the deadbirds safely. Disposal methods include composting, burial, incineration, rendering, or landfilling. Dispositions will depend on several things: the type of strain you have, the specific conditions there, State and local laws, and what you prefer.

7. Eliminate Virus
   The next step is to wipe out all traces of the virus at your property. To kill the virus, thoroughly clean and disinfect the farm, equipment, and all affected areas of your farm. You can do this work yourself or hire contractors to handle it.

8. Test
   As soon as you're ready, let your caseworker know you're finished with cleanup. Your site must then stay empty for at least 21 days. During this time, we'll return to collect and test environmental samples. We need to confirm that your property is completely virus-free.

9. Restock
   Once USDA and the State both approve, you can restock your facilities and start production again. State officials will release your farm from quarantine after all required testing and waiting periods are done.

10. Maintain Biosecurity
    After restocking, you’ll need to continue maintaining the highest biosecurity standards to keep the virus from coming back. For biosecurity tips, go to www.aphis.usda.gov/publications and download the fact sheet “Prevent Avian Influenza at Your Farm.”

How Long Does the Process Take?
Ideally, this entire process could be completed in as soon as 60–120 days. However, the timeframe varies depending on many things (for example, flock size, depopulation and disposal methods used, test results, farm’s location). We’re committed to restoring production as fast as we can while also protecting poultry health.

Questions?
Talk with your caseworker or the State or Federal officials responding to the disease event in your area.

For general information and contacts, visit:
www.usda.gov/avian_influenza.html
www.aphis.usda.gov/fadprep

Animal and Plant Health Inspection Service • APHIS 91-85-025 • Issued September 2015

USDA is an equal opportunity provider and employer.
Roles of Landfills

With billions of birds, seeking landfills that could accept:
• Bird carcasses: adults and pullets/poults (young birds)
  • Adults range from 6-8 lbs (layers & broilers) up to 80 (for tom turkeys)
• Waste products, such as manure and litter (typically shavings or pellets), egg flats, pallets
• Hatchery waste
• Leftover feed
• Eggs and egg product that cannot enter the food supply
• PPE (personal protective equipment such as Tyvek coveralls, gloves, etc.)
• Cleaning and disinfection materials/supplies
• Or any combination of the above.
Disposal needs beyond bird carcasses:

- Egg Washing System
- Candling of Eggs
- Egg Packaging System
- Eggs in Cartons and in Boxes
Management considerations at landfill:

**Leachate Management**
- Storage/recirculation/land application?
- County/state specific
- USDA white paper on risk of leachate expected summer 2016

**Operations/Logistics**
- Consider working hours, scale operations, tracking AI waste, tipping fees, billing, transportation to and from
- Scheduling delivery of waste
- Use of contractors at landfills
- Clean/disinfection/gray water management

**Public Relations/Outreach**
- MSW vs. private landfill
- Accepting waste can help protect animal and human health
- Work with State/Fed Depts of Agriculture PIO

**Regulations/Permitting**
- County/state regulations
- Modification of permits needed?
- Will permitting be handled differently in emergency/disease outbreak?
Use of contractors at landfills:

- USDA contractor responsible for logistics and biosecurity, but rely on landfill operators to assist with identifying local resources.
  - Heavy equipment rentals, power sprayer rentals, frac tanks, tents, gravel for roads and command area, wooden mats, odor control mister, portable toilets, food for workers, etc.
- Landfill needs a system for weighing and tracking AI wastes simultaneously with regular MSW receipts.
- Landfill bills USDA, contractor, or producer (depending on who hired the landfill).
Planning/Operations

• Use landfill staff or contractors for excavation and disposal activities (includes cleaning/disinfection of vehicles)?

• Amount of time necessary to excavate trenches?

• Separate areas for MSW and AI waste staging and disposal.

• Dedicated trucks and decontamination areas for the hot, warm, and cool zones (typically supplied by contractor).

• Ability of farms to stage wastes on-site to control timing of delivery to landfills.
  • Consider both space and container constraints.

• How many loads of wastes can the landfill expect to receive based on the size of farm and the amount of time it takes to depopulate and containerize wastes?

• How will landfill control odor, flies, scavenger birds/wildlife?

Landfill Challenges in 2015 IA Outbreak

• Concerns about risk of infected leachate, protection of operators, public opposition, and potential lawsuits.

• APHIS, state DNR and landfill companies developed waste acceptance criteria to address operational issues.

• APHIS, CDC and NIOSH developed safety guidelines for operators.

• APHIS developed Frequently Asked Questions for public.

• Landfill companies requested federal indemnification but it was prohibited by law.
Lessons learned in Iowa and Minnesota:

• Educate people before a disease outbreak.
• Because of the potential volume of birds and waste materials, large landfills are ideal for birds and smaller ones could take egg or hatchery waste, PPE, etc.
• States worked to modify transportation weight restrictions in case of an outbreak, allowing larger (but still safe) loads to be hauled. States rerouted trucks to avoid passing poultry farms.
• Keep documentation for HPAI operations separate.
• Consider the weather, road conditions, and any extra equipment needed.
• Odor and fly control.
• Work with USDA APHIS LPA or IMT’s Public Information Officer to craft appropriate messaging for stakeholders and public.
Support for Landfills

• For any who may be interested in accepting HPAI waste, state, federal and industry partners would work closely to ensure:
  • Worker safety, including in person training and supplying with any PPE needs. Most important!
  • Work to establish SOPs for accepting waste that will be beneficial to your operation.
  • Supply contractors if needed to bring in roll-offs and trucks, assist in tipping, cleaning and disinfection, directing traffic, and managing a staging area.
  • Landfill may be hired by a state or federal government, clean up contractor, or by a poultry grower/company.
  • We will work with you to manage public perception, prepare for town hall meetings if needed- landfills could provide a valuable public service by assisting in disposal during an outbreak.
Interested?

• USDA can supply job aids that have already been developed and can work one on one with landfills to facilitate their involvement

• To start the process of becoming a federal contractor:
  • [www.sam.gov](http://www.sam.gov)

This process can take several weeks, so please plan ahead.

Permitted Movement

FAD PReP Manual 6-0
February 2017
Overview

- Introduction
- Roles & Responsibilities
- Defining Permits & Movements
- Permit Requirements & the Gateway
- Permitting Process
Introduction

PERMITTED MOVEMENT
Permits

- *Permits* are the mechanism by which movements are allowed during a foreign animal disease (FAD) outbreak.
- These permits allow *permitted movements*.
- Permitted movement intersects both quarantine and movement control (QMC) and continuity of business (COB).
- In a disease outbreak, permits are issued to move specific transports/items into, within, and out of regulatory Control Areas (CAs).
- Permits help to achieve FAD response goals.
Permitted Movement Goals

- To facilitate the issuance of permits during an FAD outbreak.
- To implement science- and risk-based permitting guidance based on the best evidence available.
- To provide transparent information to States, stakeholders, and the public on USDA APHIS permitted movement processes.
- To use the Emergency Management Response System 2.0 (EMRS2), the official USDA system of record, for issuing permits and tracking movements into, within, and out of a regulatory CA during an FAD incident/outbreak.
- To ensure permit data is entered into EMRS2 in an accurate and timely manner, reflecting best practices and standards.
- To provide personnel to unified Incident Command and/or State(s) as requested by State(s) to support permitting activities in EMRS2 during an FAD outbreak.
Roles & Responsibilities

PERMITTED MOVEMENT

United States Department of Agriculture
State Role: During an Incident

- USDA APHIS recommends States use EMRS2 for permitting activities.
- If a State feels as if they have a permitting and information management system that can handle a potentially large number of requests rapidly, and can communicate to other States to receive approval for interstate movements, the State can use their system to permit movements and issue permits in an outbreak.
- If a State uses their own system, they must communicate data to the unified Incident Command for entry in EMRS2.
State Role: Requesting USDA APHIS Support

- As seen in two recent outbreaks of highly pathogenic avian influenza in the United States, permitting can become a monumental task.
- In these outbreaks, multiple States requested USDA APHIS assistance for permitting activities.
- USDA APHIS is prepared to support permitting activities in EMRS2 for any State experiencing an FAD outbreak, upon their request.
State Role: Additional State Requirements

- States may also establish additional enhanced active surveillance, testing criteria, or permit requirements for premises located in the Surveillance Zones/Free Areas within their State (outside of any regulatory CA).
- Any existing entry requirements that States have in place prior to an outbreak must also be met for interstate movements on Interstate Certificates of Veterinary Inspection, in addition to specific FAD permit requirements.
- Movements outside the scope of the CA during an FAD outbreak are not captured in EMRS2 and should continue under existing authorities, processes, procedures, and guidance.
USDA APHIS Role: During an Incident

- State(s) have primary authority (absent a USDA Extraordinary Emergency Declaration or similar); USDA APHIS—in coordination with State Animal Health Officials and the unified Incident Command—provides the oversight for interstate permitted movement (commerce) and any movement relating to international trade.

- USDA APHIS is prepared to support State(s) in an FAD incident in all permitted movement activities, as requested by the State, using EMRS2 and skilled EMRS2 personnel.
Defining Permits & Movements

PERMITTED MOVEMENT
Permits

- A permit (can be paper, electronic, or both) is used to approve and document movements into, within, and out of a regulatory CA.

- A permit conveys two critical pieces of information:
  1. approval for a movement (from a specific origin point A to a specific destination point B), and
  2. approval for a specific item associated with this movement (animals, products, materials, etc.).

- A permit typically also defines specific requirements that must be met for movement (e.g., diagnostic testing).

- A permit must be approved by the origin and destination State.
Types of Permits

There are two primary types of permits (all entered in EMRS2):

1. **Specific permits** are based on risk and are related to controlling and containing the FAD outbreak, particularly for biocontainment (i.e., keeping the disease on Infected Premises) and bioexclusion (i.e., keeping the disease out of non-infected premises).

2. **COB permits** are for maintaining business continuity in an outbreak for premises that are affected by movement restrictions but not infected by the FAD agent. Split into two types: operational and Secure Food Supply (SFS) for normal movements and animals/animal products, respectively.
Three Types of Movements

1. **Permitted movements** are those movements associated with an approved permit.

2. **Tracked conveyances** are negligible-risk movements that are tracked in EMRS2, but do not require a permit (typically from Food Safety and Inspection Service [FSIS]-inspected plants).

3. **Routine movements** are not tracked in EMRS2 and do not require a permit, though the producer may be required to keep enhanced records of these movements.
Overview

- There are seven key pieces of information that are required to obtain any type of permit.
- These data are recorded in EMRS2 in as close to real time as possible during an FAD outbreak.
- During an outbreak, additional data standards may be defined.
- If a State elects to use an information system other than EMRS2 to issue permits in an outbreak, these data must be communicated to the unified Incident Command for import or entry into EMRS2.
Information Required for a Permit

1. **Permit Class**—location, e.g., into CA, out of CA, or within CA.
2. **Permit Reason**—reason for permit, e.g., direct to farm, direct to landfill, or into commerce.
3. **Origin Premises**—Must be in EMRS2.
4. **Destination Premises**—Must be in EMRS2.
5. **Items**—What is allowed to move, e.g., manure/litter, feed, eggs, groups of animals.
6. **Item Class**—Further description of item, e.g., if the item permitted was “groups of animals,” the item class offers further information.
7. **Duration/Span of Permit**—First movement date, as well as how long the permit is valid for.
Additional Requirements
Prior to Movement

- Permits and their associated permitted movement may have additional requirements that must be met before the movement is made.
- These records and documentation can be uploaded in EMRS2 for review by relevant parties.
- For example, diagnostic testing or mortality reports from the premises may be required.
- Diagnostic testing results can be entered into EMRS2 or automatically messaged, if the testing laboratory can message results (strongly preferred), and attached to the origin premises in EMRS2.
EMRS2 Customer Permit Gateway

Introduction

- The EMRS2 Customer Permit Gateway, also referred to as “the Gateway,” is a new, producer-facing portal that provides an automated linkage from a website to the EMRS2 system.
- The Gateway is an interactive, secure, web application, where registered producers can create a permit request for movement.
General Information & Benefits

- The Gateway has important benefits and greatly streamlines the permitting process:
  - It offers producers a way to see the real-time status of their permit requests.
  - It facilitates timely and accurate data entry into EMRS2, the USDA APHIS official system of record for FAD outbreaks.

- The use of the Gateway does not change the overall permitted movement process or permitting concepts.

Permitting Process
Overview

➢ There are eight general steps involved in permitting.
➢ The process is broadly the same regardless of the type of permit—specific or COB.
➢ Remember, a tracked conveyance does not require a permit for movement, but is typically entered in EMRS2 and available for the origin State and destination State to review in EMRS2.
STEP 1: Permit Request

Permitting Process

- Permit Request
- Accepted Permit Request
- Pending Permit
- Reviewed Permit
- Approved Permit
Specific Permit Request

- The unified Incident Command determines if a permit is required for movement; the producer needing to make the movement or the unified Incident Command can initiate the permit request.

- At this time, specific permit requests are not made through the Gateway and should be made through normal communication channels.

- Specific permits may receive priority for review in the permit request queue, as they relate directly to response operations and the containment/elimination of the FAD.
Continuity of Business Permit Request

- COB permits must be requested by the producer.
- It is preferable that these requests are made through the Gateway; if a producer is not registered, all other existing methods can be used to make a permit request.
- It is highly recommended that producers with potentially large volumes of SFS permitted movements register in the Gateway.
STEP 2: Enter/Confirm Data in EMRS2
Data Review

- For both types of permits (specific and COB), personnel in the origin State and/or unified Incident Command personnel review the data entered for the permit request only for completeness.

- For specific permits not requested through the Gateway, personnel must create a new permit request (enter data in EMRS2) in the permit request queue.

- For COB permit (operational or SFS) requests through the Gateway, the data does not need to be entered in EMRS2: it appears automatically in the permit request queue once submitted by the producer in the Gateway.

- As soon as the data is complete, the permit request is accepted and continues forward as a pending permit.
STEP 3: Review Pending Permit and Documentation
Pending Permit Review

- The review of the pending permit is substantive and requires trained personnel that understand permit requirements.
- For interstate movements, Step 3 (review) and Step 5 (approval/denial) are both required for all pending permits, regardless of permit type.
- However, for pending permits that are for intrastate movements, since the origin State and destination State are the same, Step 3 and Step 5 are inherently combined.
Origin State Options

The origin State has three options at this stage for the pending permit (for interstate movements):

1. Status the pending permit as a “Reviewed Permit;” present and recommend approval to destination State.
2. Status the pending permit as a “Reviewed Permit;” present but do not recommend approval to destination State.
3. Reject the pending permit (for example, if the premises has not met the requirements to move items out of the CA); do not present pending permit to the destination State.
STEP 4: Origin State Notifies Destination State of Reviewed Permit

Permit Request → Accepted Permit Request → Pending Permit → Reviewed Permit → Approved Permit

Permitting Process
Reviewed Permit Notification

- After the origin State reviews the pending permit, the destination State (if different than origin) is notified that there is a reviewed permit.
- All notifications can be done automatically via EMRS2.
- If the origin State elects to use their own information management system for permitting, they must also have a way to document notifications to the destination State.
- If needed, in a large outbreak, an established National Permitting Unit can also streamline this process for origin State(s).
STEP 5: Destination State Approves or Denies Permit
Approval or Denial of Permit

- For any permit that is proposing interstate permitted movement—whether specific or COB (operational or SFS)—the destination State always has the opportunity to approve or deny the reviewed permit.
- Destination State is also responsible for confirming permit is acceptable with the destination premises.
- When a reviewed permit is approved by the destination State, it becomes an “Approved Permit.”
- If the permit is denied, the permit process ends.
- If the destination State approves the reviewed permit, the destination State enters an “approved” date and an “expiration” date.
Attached Documentation

- When there are criteria required for the permit, like diagnostic testing results, the destination State can elect to review any/all documentation related to these criteria.

- Supplementary, required documentation can be sent to the destination State directly by the producer or origin State; it is preferable that any such documentation is uploaded in EMRS2 for all parties to review.
Revoking a Permit

- It is important to note that if the epidemiological situation changes, or at the destination State’s discretion, a permit may be revoked at any time.

- States are encouraged to make their decisions based on the best science- and risk-based information available during an FAD outbreak.

- Both destination and origin States can revoke a permit in EMRS2, or can contact EMRS2 personnel or the unified Incident Command to revoke a permit.
STEP 6: Destination State Notifies Origin State of Decision
Notification of Approval or Denial

- For any reviewed permit that requires destination State approval, the destination State must notify the origin State whether they approved or denied the reviewed permit.

- This formal notification also serves as further documentation that the destination State received notice of a reviewed permit and responded.

- This step is critically important so that States cannot claim that movements were made without the approval of the destination State.
STEP 7: Origin State/Unified Incident Command Issues Permit
Permit Issuance

- Once the reviewed permit is granted approval and the destination State notifies the origin State of the decision, the permit can be created in EMRS2.
- For specific permits, the unified Incident Command or origin State personnel familiar with EMRS2 typically produce the permit form in EMRS2.
- For COB permits, the origin State typically creates the permit form in EMRS2; permit templates can be customized, including with State logos.
- Permits can be issued immediately (PDF).
STEP 8: Permitted Movement Occurs
Permitted Movement Occurs

- Once a permit is approved, specific conditions are met, and notification of the forthcoming permitted movement has occurred, the actual movement can occur.
- This movement may occur once (common for specific permits) or multiple times (common for COB permits).
- It is the producer’s responsibility to ensure that all requirements are entered prior to movement.
- It is the destination State’s responsibility to review and request documentation from the origin State/producer when necessary.
SUMMARY OF PERMITTING PROCESS
Overview of the Eight Steps in Permitted Movement

Step 1
Unified Incident Command or Producer submits permit request

Step 2
Unified Incident Command or origin State enters/checks data in EMRS2 and accept permit request, creating a pending permit

Step 3
Unified Incident Command or origin State reviews pending permit and documentation

Step 4
Origin State notifies the destination State of reviewed permit
Overview of the Eight Steps in Permitted Movement, continued

Permitting Process

Destination State reviews and **denies permit** and notifies the origin State of their decision.

**Step 5**

**Step 6**

Destination State reviews and **approves permit** and notifies the origin State of their decision.

**Step 7**

The origin State or Unified Incident Command **issues approved permit**.

**Step 8**

Movement occurs.
Overview of COB Permit Process using the EMRS Customer Permit Gateway

Permitting Process

Step 1: Producers registered in the Gateway can create a permit request after logging in.

Step 2: After quick data review, pending permit gets sent to the origin State for review in EMRS2.

Step 3: The reviewed permit is then shared with the destination State to be either rejected or approved.

Step 4: Destination State approves permit and notifies origin State.

Step 5: Per the approved permit, producers enter movement(s) in the Gateway.

Step 6: Movement(s) Completed

Step 7: Approved permit issued; producers can now download their permit from the Gateway.

Step 8: Producers registered in the Gateway can create a permit request after logging in.

Producers

Producers can log-in at any time to view status.

Move items
For Further Assistance

- Additional training or materials can be requested by contacting the EMRS National Coordinator or their EMRS Network Associate for their District.
- States should not hesitate to reach out if they feel as if they are unprepared to use EMRS2 in an outbreak and need additional assistance.
- In addition, at any point during an outbreak, APHIS Veterinary Services personnel are ready to assist States as requested.

Definitions

Bio-Zip™ Liner

Bio-containment bags which are constructed of a thermally-bonded layering of polypropylene and featuring an industrial zippering system. The Bio-Zip™ Sealable Liners fit securely inside industrial roll-off containers, trailers or truck racks from 10 to 40 cubic yards in total volume. They are used to manage large volume biological and organic waste streams and the associated odor, leakage, disease and environmental contamination issues. **Disclaimer: The document is not endorsing the product of a specific vendor, but merely used the data on this product as an example.**

Carcass

The body of an animal that has died or been killed, and is not being slaughtered for human or animal consumption.

Collecting station

An establishment where carcasses may be placed for temporary holding until loaded on trucks.

Confirmed positive case (of FMD)

An animal with clinical signs consistent with FMD and from which FMDv is isolated and identified in a USDA laboratory or other laboratory designated by the Secretary of Agriculture.

Control Area

Consists of an infected zone and a buffer zone. Initially, the entire State, Commonwealth, Tribal Nation, or territory may be declared a control area and subject to movement restrictions until appropriate surveillance and epidemiological evidence has been evaluated and the extent of the outbreak is known.

Decomposition

The process by which organic substances are broken down into simpler forms of matter

Dump Truck

A standard dump truck is equipped with an open-box bed, which is hinged at the rear and equipped with hydraulic pistons to lift the front, allowing the material in
the bed to be deposited on the ground behind the truck at the site of delivery. The truck does not have a sealed tailgate.

**Fomites**
Inanimate objects that, when contaminated with a viable disease agent, can serve as a source of infection for a susceptible host.

**Grapple**
A hydro-mechanical device able to rotate on an axis with a clamshell or bucket attached at the end of the boom, which is intended for the collection of large items, in this case carcasses.

**Hazardous Material**
A substance or material that the Secretary of Transportation has determined is capable of posing an unreasonable risk to health, safety, and property when transported in commerce, and has designated as hazardous under section 5103 of Federal hazardous materials transportation law (49 U.S.C. 5103). The term includes hazardous substances, hazardous wastes, marine pollutants, elevated temperature materials, materials designated as hazardous in the Hazardous Materials Table of 49 CFR 172.101), and materials that meet the defining criteria for hazard classes and divisions in part 173 of subchapter C of this chapter.

**Herd**
The population of animals at defined premises.

**Incubation period**
The known or assumed period between the introduction of a pathogen into a susceptible animal and the occurrence of the first clinical signs of the disease; the OIE standard for FMD is 14 days.

**ID$_{50}$**
Infectious Dose 50; amount of pathogen measured as number of colony forming units (CFU) for bacteria or number of virus particles required to infect 50% of exposed individuals.

**Index premises**
The first premises known to have a case of FMD during the outbreak under investigation. The true index premises are the premises with the first actual case in an outbreak; it is often not definitively determined.

**Infected premises**
Premises where a presumptive positive case or confirmed positive case exists based on laboratory results, compatible clinical signs, case definition, and international standards

Leakage The body fluids that have the potential to leak from the intact carcass post-mortem. These include feces, urine, stomach/rumen contents, blood, saliva, and milk spillage

Leachate Liquid that is produced by the decomposition of livestock carcasses and seeps from the carcasses.

Leak-Proof Liner

A temporary durable sheet lining (made of plastic, vinyl, etc.) placed in the container of the truck and used to protect the bed and sidewalls of the cargo space of truck trailers

PFU Plaque-forming unit; used in virology studies to estimate the quantity of viral particles present in a sample based on the number of plaques formed per unit volume.

Premises A location where livestock are raised, housed, or pass through during commerce.

Rendering truck

Tractor-trailer truck with detachable trailer box and a leak-proof tailgate specifically designed for rendering. Trailer specifications can vary in length from 26 to 40 feet (most common are 28, 32 and 40 feet) with standard width of 8 feet and height of 12 feet.

Roll-Off Truck

Tractor-trailer truck with detachable box trailer which is able to be removed from the trailer component. They are characterized by a rectangular footprint, utilizing wheels to facilitate rolling the trailer in place. The open top container is designed to be transported by special roll-off trucks. As the roll-off truck raises its hydraulically operated bed, the roll-off container rolls off of the bed. A cable is used to slowly lower the container. These can operate on a winch system or a hook-lift system.
Saprophytic decomposition/putrefaction

One of the stages of decomposition, produced mainly by the action of bacterial enzymes, mostly anaerobic organisms derived from the gastrointestinal tract, causing hemolysis, disintegration of tissue, and gas formation in blood vessels and tissue spaces.

Stamping out

Depopulation of clinically affected and all presumed exposed susceptible animals.

Spillage

Seeping of carcass fluids from the carcass to the truck and then to the environment.

Tarp

A sheet of material, such as waterproofed canvas, vinyl coated polyester mesh, etc. which is used to cover the open trailer to protect contents from visibility or ejection of material.

TCID$_{50}$

Tissue Culture Infective Dose 50; amount of a pathogen measured as number of virus particles required to produce pathological change in 50% of cell cultures inoculated, expressed as TCID$_{50}$/mL.

Truck

A vehicle or conveyance used for the transportation of carcasses.

Stages of disease:

Infected

Includes all stages of disease (L+I+C): latent (L), pre-clinically infected (I) and clinically infected (C).

Viremic

Active virus circulating in the bloodstream. Susceptible species can be viremic and shedding virus before they develop clinical signs. Includes the pre-clinical (I) and clinical (C) stages of disease in this risk assessment.

Incubation period

Time from exposure to the development of clinical signs.

Pre-clinically infected stage (I)

Animal is viremic, is shedding virus, but does not have clinical signs. These animals represent the highest risk for spread of virus.
Clinically infected stage (C)

Animal is viremic, shedding virus and is exhibiting clinical signs of disease.

Latent (L) Susceptible animal that has been exposed and is incubating the virus, but is not viremic.

Recovered (R)

No longer infected with the virus.

Susceptible (S)

Healthy animal likely to be exposed to the virus.
Executive Summary

The present risk assessment proactively evaluated the risk of infecting susceptible livestock by the movement of Foot and Mouth Disease (FMD) infected carcasses (swine and cattle) from FMD infected premises. The risk assessment evaluated the most up to date available science and solicited opinion from experts when data was lacking. This risk assessment is proactive in nature and the scenarios, pathways and depopulation practices assessed were based on the current practices and regulations applicable during an animal disease outbreak in the US. The characteristics, types of conveyance methods, and equipment used to transport the infected carcasses were provided from expert opinion and verified through site visits. Different modeling techniques were used to estimate the number of infected animals during a FMD outbreak at various time intervals, the total time estimated from infection to depopulation and the total amount of FMD virus (FMDv) contained in a disposal truck. The main outcomes of the risk assessment should be reviewed if needed as new data becomes available in the future.

Risk estimation: The risk of FMD infection of susceptible livestock associated with the movement of swine and cattle carcasses from FMD infected premises to a disposal site during a FMD outbreak in the United States is negligible when using a standard rendering truck (tailgate sealed and tarp cover) and a Bio-Zip™ bag, and between negligible and low when using a standard rendering truck or a roll-off/dump truck with a Bio-Zip™ bag. The risk level in other scenarios (uncovered standard rendering trucks, uncovered roll-off/dump trucks, covered roll-off/dump trucks and a liner) is between moderate and high.

Main results: Time for FMD detection was estimated by a disease spread model to be between 4-10 days for swine and beef cattle and 3-9 days for dairy cattle premises of different sizes. Total time from infection to depopulation (including detection and confirmation) for the first FMD infected case was estimated to be between 10-15 days for swine, 8-12 days for dairy and 10-14 days for beef cattle premises. Total time estimated for subsequent FMD cases was between 7-12 days for swine, 6-9 for dairy and 8-11 days for beef cattle premises. Most of the animals (>65% for the first case and >81% for subsequent cases) were viremic at the time of depopulation. The average concentration of FMDv in a carcass in experimental inoculation studies was $10^3$ Plaque-Forming Unit per gram (PFU/g) for a pig carcass and $10^6$ PFU/g for a cattle carcass. The total amount of infected carcasses moved to the disposal site (relative to the size of the animal carcass and the capacity of the truck trailer) was between 23-390 cattle carcasses and 117-780 pig carcasses per truck. Any small amount of body fluids (1 mL) would contain virus that is equal and greatly exceeds the infective dose by oral and inhalation route for pigs and cattle. The likelihood that swine and cattle carcasses moved from FMD positive premises will contain an infective dose was high. The use of a Bio-Zip™ bag in a standard rendering truck (tailgate sealed and tarp cover) reduces the likelihood of leakage, spillage and aerosolization to negligible.
1. Background

This risk assessment was performed by the University of Minnesota’s Center for Animal Health and Food Safety to proactively evaluate the risk of moving swine and cattle carcasses to an offsite disposal location, from a Foot and Mouth Disease (FMD) confirmed positive premises during a FMD outbreak in the United States (US), as it relates to potential spread to susceptible livestock.

In the event of a FMD outbreak in the US, Local, State and Federal authorities will implement a foreign animal disease emergency response as described in the USDA Animal and Plant Health Inspection Service (APHIS) Framework for Foreign Animal Disease Preparedness and Response Plan (USDA FAD PReP). This response includes a control and eradication strategy that will utilize depopulation, quarantine, vaccination, and movement control measures applied throughout the swine and cattle industry. If depopulation is utilized, due to the large amount of biomass from carcasses and potential limitations on the premises of origin for disposal, there may be a need to transport carcasses offsite for disposal. This movement has the potential to result in virus spread to other uninfected premises and susceptible livestock.

Risk assessment in the animal health context comprises a framework that uses a tool set and available scientific information to assess the situational level of risk to the health of an animal population and the potential consequences. Completing this type of risk assessment in a timely manner during an outbreak is typically impractical. Risk assessment conducted proactively, before an outbreak occurs, provides the framework necessary for decision makers to identify the risk pathways for disease transmission. They are thus equipped to quickly assess the effectiveness of the current practices, preventive measures and additional mitigation measures, if needed, as they pertain to the risk associated with the movement of an agricultural commodity.
2. Scope

The purpose of this risk assessment is to determine the risk of FMDv infection of susceptible livestock associated with the movement of swine and cattle carcasses from a FMD-infected premise to an off-site disposal facility during a FMD outbreak in the United States. The risk evaluation is based on the likelihood of FMDv being present in the carcasses at the time of transportation and the likelihood their movement could serve as a source of infection for susceptible livestock. The risk assessment evaluates the likelihood that: 1) the swine and cattle carcasses from a FMD-infected premises will contain an infective FMDv dose after completion of euthanasia; 2) FMDv could be released into the environment from the carcasses through post-mortem leakage of infected body fluids and/or aerosolization of infectious particles from the body fluids; and 3) susceptible livestock will be infected by FMDv during the transportation of carcasses from the infected premises to the disposal site.

The primary mode of transportation evaluated for carcass movement from the FMD-infected premises of origin directly to a disposal site is a rendering truck. This is defined as a tractor-trailer truck equipped with a box trailer (lengths of 28 ft, 32 ft, or 40 ft) that has a sealed, leak-proof tailgate and is open on the top. The second type of truck that will be considered in this risk assessment is the roll-off truck. This truck has a removable open-top, box trailer that is fitted onto a rectangular footprint and utilizes wheels to facilitate rolling the trailer into place. The third type of truck that will be considered is the dump truck. A standard dump truck is equipped with an open-box bed, which is hinged at the rear and equipped with hydraulic pistons to lift the front, allowing the material in the bed to be deposited on the ground behind the truck at the site of delivery. The standard rendering truck, roll-off and dump truck will be considered with and without the following mitigations (one or in combination) that can be used in conjunction with the standard trailer:

1) Tarp covering
2) Bio-Zip™, leak-proof carcass bags
3) Leak-proof liner (only for roll-off and dump trucks)

For each of the transportation modes, the following release and exposure pathways were addressed:

- Cross-contamination of trucks, personnel and equipment from carcass fluids contaminated with FMDv escaping from the conveyance.
- Aerosol transmission of FMDv particles escaping from the conveyance.
3. Assumptions

A conservative approach using the “worst-case” scenario was used in this risk assessment. Literature data on FMDv concentration in swine and cattle carcass tissues consider animals artificially inoculated with FMDv at high concentrations, which may not represent the reality of a naturally occurring outbreak.

This risk assessment takes into consideration all applicable regulations, including preventive measures already in place, as well as additional preventive measures that could be implemented during an outbreak. This assessment is proactive in nature and cannot address the specific circumstances surrounding an outbreak in detail. Therefore, we are making some assumptions to establish context and applicability. These assumptions are:

- A FMD outbreak in the United States in the commercial pig and/or cattle (beef or dairy) population has occurred.
- A swine or cattle farm has been confirmed as a FMD-infected premises and a specific euthanasia protocol has been established as the depopulation method.
- All animals in the infected premises will be euthanized and moved to disposal offsite as intact carcasses.
- All disposal options have been predetermined so that the time to locate is not part of the delay of the disposal.
- Time to complete indemnity was not included in the estimation of total time from infection to depopulation due to the assumption that this is not a time limiting step.
- The movement considered will be from one infected premises directly to the disposal site, without any subsequent stops along the route.
- The same trucks, personnel and/or equipment will not be shared among multiple infected premises without complete cleaning and disinfection.
- Carcasses will be moved immediately after euthanasia, so environmental factors (temperature, pH) will not have an effect on FMDv concentration in the carcass.
- Post-mortem autolysis will occur, and there will be some leakage of fluids from the intact carcasses. As fresh carcasses will be moved immediately after euthanasia, there will be little saprophytic decomposition/putrefaction. We assume minimal rigor mortis at the onset of loading due to the short time between euthanasia and carcass loading.
- The tarp (roll-off or drawn down) will be appropriately cleaned and disinfected prior to each load and following each unloading or there will be a new tarp utilized for each trip.
- Options and mitigations evaluated were provided to the risk assessment team and were evaluated for their impact on the risk pathways. They were not evaluated for their functionality. We assume all mitigations considered (e.g. Bio-Zip™ bag, liner, tarp,
equipment, cleaning and disinfection procedures) will function appropriately and/or be performed according to their specifications.

- The exterior surfaces of trucks and tires will be cleaned and disinfected prior to leaving the infected premises, as well as at disposal area following drop off, and will follow accepted procedures outlined in the USDA APHIS FAD Prep Guidance (USDA FAD PReP)
- Wildlife population pathways will not be considered in this risk assessment.
- Roads taken by the disposal trucks will be shared with the open traffic.
- All vehicles will be in compliance with federal and applicable state Department of Transportation (DOT) regulations and APHIS carcass transportation regulations, including that all vehicles used in transportation of carcasses will be leak-proof.
- The driver of the carcass truck will not come into contact with any carcasses or infected equipment while on the infected premises, the carcass loading area or the carcass unloading areas at the disposal site.

4. Overview of data analysis approaches

Risk Assessment Overview

This risk assessment is based on the OIE guidelines and methodology for import risk analysis with some modifications (OIE, 2004). The OIE model is comprised of hazard identification and three steps within a risk assessment: 1) entry assessment (release of virus to the environment through the carcasses); 2) exposure assessment (exposure of susceptible animals); and 3) risk evaluation (considers the entry and exposure assessments to provide the overall risk estimation).

The emphasis of this risk assessment is the release of FMDv associated with the movement of swine and cattle carcasses from a FMD positive premises and exposure of susceptible livestock. If the entry assessment demonstrates a negligible likelihood of the carcass being contaminated with FMDv, the risk assessment may be concluded. However, if the risk is estimated to be greater than negligible, the next step in the risk assessment is the exposure assessment, which would assess the likelihood that susceptible animals will be infected by FMDv through the movement of carcasses from FMD positive premises.

As recommended by the OIE, the risk analysis process is described as follows:

- Hazard identification is the process of identifying and understanding the biology and epidemiology of FMD and FMDv to determine whether the agent is a hazard under specified situations.
- Entry assessment determines the likelihood of an agricultural commodity (e.g. carcass) being infected or contaminated with a hazard (e.g. FMDv) and describes the biological pathways
necessary for that hazard to be introduced into a particular environment with susceptible livestock. It includes an estimation of the likelihood (i.e. qualitative or quantitative) of each of the pathways.

- Exposure assessment describes the biological pathway(s) necessary for exposure of animals to the identified hazard (e.g. FMDv) and estimates the likelihood of those exposures occurring.

- Risk estimation consists of integrating the results from the entry and exposure assessments to produce summary measures of the risk associated with the identified hazard.

**Likelihood and risk evaluation**

The likelihood for each pathway was assessed and categorized using the descriptive scale in Table 1 below:

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Descriptive Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>High</td>
<td>The event is very likely to occur</td>
</tr>
<tr>
<td>Moderate</td>
<td>The event is unlikely but does occur with a certain probability</td>
</tr>
<tr>
<td>Low</td>
<td>The event is unlikely to occur</td>
</tr>
<tr>
<td>Negligible</td>
<td>The likelihood that the event will occur is insignificant, not worth considering</td>
</tr>
</tbody>
</table>

The risk estimation was based on the summarization of the likelihoods for each pathway in the entry and exposure assessments.

**Uncertainty estimation**

The uncertainty of the likelihood/risk estimation was assessed by using a range within the descriptive definitions in Table 1. When uncertainty about the estimation was low (the estimation was somewhat certain), only one descriptive definition was used to estimate the likelihood/risk (e.g., low, high). When the uncertainty on the estimation was moderate or high the descriptive definition used to estimate the likelihood/risk was within a range (e.g., between moderate and high), the range being broader as the uncertainty about the estimation was higher.

**Modeling Overview**

A within herd stochastic disease spread model was applied to simulate the transmission of FMDv within a group and estimate the number of pigs, dairy cattle and beef cattle in various disease states at each time period. The disease states include: susceptible (S), latent (L), pre-clinically infectious (PI), clinically infectious (CI) and recovered (R) (Carpenter TE, 2004).
Estimates of animal level disease stage durations (latent, preclinical, clinical, and recovered) were obtained from recently developed parameters used in the NAADSM (North American Animal Disease Spread Model) (USDA, 2012). The main outputs of the model were time for detection at different farm size scenarios and to simulate the number of viremic (pre-clinically and clinically infectious) and recovered animals that would be moved to the disposal site.

The model updates the number of animals in each disease state every 6 hours, which increases the accuracy of detection. The uncertainties in input variables, as well as the inherent variability associated with the course of infection in individual populations and the spread within the group, are considered in the model. Appendix A: Model Disease Spread presents the assumptions, definitions and background information used in the disease transmission model.

The detection module of the disease spread model estimates the time to detect FMD infection in the group based on heightened active observational surveillance for clinical signs, one of the mitigation measures that may be applied in an outbreak at the herd level. The model “checks” or applies specific detection mechanisms at user specified time steps (e.g., every day or twice per day). FMDV infection may be detected in a time period based on the specific detection mechanism and the number of clinically infectious animals.

Inputs for the disease spread model in the form of probability distributions for each disease state (latent, pre-clinical and clinical) for the transmission of FMDV within swine, dairy and beef cattle populations were obtained from an APHIS study where data from different FMD studies were analyzed by meta-analysis to estimate the probability distributions ((USDA 2012); (USDA, APHIS, NAHMS, 2012)).

5. FMD Depopulation Procedures and Carcass Movement

5.1. Standard Operating Procedures for FMD Depopulation

In infected premises that are being depopulated, the goals are to prevent contact between FMDV and susceptible animals, as well as to stop the production of FMDV in exposed or infected animals. The response strategy of stamping out infected premises is being considered in this risk assessment. This would be the case for an outbreak that is contained in jurisdictional areas in which FMD can be readily contained and further spread is unlikely. Stamping out is the preferred depopulation method for clinically infected and in-contact susceptible animals as a means to reduce the potential of disease spread. For purposes of this risk assessment, we assume the depopulation procedures will follow the USDA FAD PreP Guidance (USDA FAD PReP).
The standard operating procedures during depopulation are that the driver arrives at the site with the vehicle and makes contact with the officials/on-site command at the infected site. Many rendering industries utilize rendering trucks that are equipped with their own carcass lift arms and clam buckets (grapple systems) (Figure 1). These can be operated by the driver and although may need to leave the truck cabin to operate the lift, the driver will not step foot on the ground, nor have any contact with the carcasses.

Figure 1: Standard Rendering Truck with Grapple System

Image courtesy of Redwood Metal Works (http://redwoodmetalworks.com/)

Figure 2: Grapple truck with dump trailer.

In cases where a forklift or front-end loader is used to lift an entire dump container and empty its contents into the trailer, an on-site operator (not the truck driver) would operate that machinery. If applicable, the driver would then cover the trailer using the roller tarp, operated from the front of the trailer (Figure 2).

During an outbreak, it is assumed that the driver never leaves the vehicle while on the infected premises (loading area). If duties cannot be performed by the driver from the cabin or platforms of the vehicle and would require the driver to be on the ground, personnel on the ground will load the vehicle and pull the tarp over the container. This tarp would be drawn tight in order to reduce air flow (although it still would not be 100% air-tight). In the US, it is required for trucks to be leak-proof while hauling animal carcasses (see 9 CFR 325.21 - Means of conveyance in which dead, dying, disabled, or diseased livestock and parts of carcasses thereof shall be transported (Code of Federal Regulations and Federal Register).

For purposes of this risk assessment, the assumption is that euthanasia would take place only when there is a dedicated destination for the carcass disposal. This means that euthanasia will take place within a matter of minutes to hours prior to the carcasses being transported to the destination. The time limiting factor in a depopulation scheme is disposal rate, especially for large operations where burial on site is not an option. Storage of carcasses creates another set of problems for landfills, rendering, and hauling (more liquids) unless chilled. Therefore, simultaneous euthanasia and disposal will be the operational plan considered for this risk assessment.

Estimates for depopulation rates and timing for depopulation procedures are not available in the literature. Expert opinion was thus solicited for euthanasia and depopulation times. Experts in the field were contacted to provide their input on starting times for euthanasia for: 1) FMD Index premises, 2) subsequent FMD-infected premises, and 3) most likely depopulations rates for both swine and cattle (head/hour). A range (minimum, most likely, and maximum) was requested for each of the times and rates. See Appendix E: Expert Opinion – Depopulation for more information. These data are summarized in the table below.

</table>

*: Assuming the outbreak is localized, and all the resources are available.

**: Using the longest time when a range was provided.

**: Using 3 eight men crews (20 h +4 h cleaning), 2 ten cow side discharge alleys and 2 loaders

Time to transport the depopulation equipment and to set-up for the depopulation is a likely range of 24 to 48 hours. The time required to move animals into position for depopulation should also be taken into consideration. Once equipment and animals are in position and the depopulation procedures are ready to begin, the next time-limiting factor is the speed of the depopulation technology chosen. Table 3 below shows several of these technologies and their estimated speed.

**Table 3: Expert opinion on depopulation technology time efficiency**

<td>Estimate is 30 head/h depending on the experience of the operator and their tolerance</td>
</tr>
<tr>
<td>On farm CO₂ gassing of swine in roll-off trailers or constructed chambers</td>
<td>Dependent upon the size of the chamber or trailer, and size of animal, to determine batch size. It usually will take about 15 minutes for the euthanasia process for each batch.</td>
</tr>
<tr>
<td>Transport to slaughter plant but divert line to disposal rather than processing</td>
<td>Estimate is the line speed of the plant whether using CO₂/bolt or electric paddles*</td>
</tr>
</tbody>
</table>

*This option is not likely applicable to the situation being evaluated in this assessment, unless the premise is a slaughter facility.

Assuming the outbreak is localized and all resources for depopulation are available, in larger premises and feeder premises the process to completely depopulate the premises may be slowed due to disposal and indemnity issues. Depopulation efforts must be directly linked to the rate of...
disposal. The speed of euthanasia should not exceed the disposal rate. The disposal rate may be increased either through contracting multiple disposal options.

### 5.2. Types of Transportation

This risk assessment addresses mass depopulation at the infected premises site, with subsequent removal of carcasses from the infected premises using a standard rendering truck as conveyance. As defined for this risk assessment, the standard rendering truck is a tractor-trailer that is used to haul carcasses. This is a tractor-trailer truck (semi-truck) with an attached box trailer. The box trailers are constructed of aluminum, smooth wall panels or stakes and sheets of aluminum or steel. The trailers have a one-piece lift-off hinged doors or side swing tailgates, both of which are sealed and leak-proof, as required by federal law (9 CFR 325.21, Code of Federal Regulations and Federal Register). Standard trailers are 96 inches wide, with side heights of 5 ft or 6 ft smooth wall, double panel. The trailer lengths vary from 26 ft to 40 ft. and may be double- or triple axel. The most commonly used lengths in rendering industry practices are the 28, 32 and 40 ft trailers, which can haul 40000, 45000, and 50000 lbs., respectively.

![Standard Rendering Truck and Trailer](http://www.walinga.com/index.php?id=223)
Another option to the open-top trailer of the standard rendering truck is a trailer that is equipped with tarps systems. Tarps can be built in sizes that can accommodate dump trucks, roll off containers, dumpsters, and open top containers. Tarp cover systems can be constructed from range of materials including mesh, PVC or vinyl. In addition, tarp systems can come in a variety of formats including a sliding cable system, flip tarp system, rolling system, and solid waste tarps (tie-down system). Utilization of a tarp system is standard practice in states where law mandates that the top of the trailer be covered during carcass transportation to prevent leakage. Although the tarp reduces airflow, it is not airtight, and air will still flow over the carcasses. The tarp also helps to control scavengers. Other options are to have the trailer built with manual, air or hydraulic cylinder control lids, which tend to be less common.

For the purpose of lifting the carcasses into the trailer, trucks can be equipped with heavy duty hydraulic lift arms and buckets. Many farms will have a ‘dump container’ that is used to hold routine mortalities until the render haul truck arrives. The dump container could be used in the case of small premises depopulation. A forklift or front-end loader can also be used to lift the entire container in order to dump the carcasses into the truck’s container.

There are other secondary types of trucks that can be used to transport carcasses, such as a roll-off truck. A roll-off truck is a tractor-trailer truck with detachable open-top box container, which is characterized by a rectangular footprint and wheels that facilitate rolling the container into position. As the roll-off truck raises its hydraulically operated bed, the container rolls off, and a cable is used to slowly lower it. These operate on a winch or hook-lift system.
The third type of truck trailer that will be considered in this risk assessment is the dump truck. A standard dump truck is equipped with an open-box bed, which is hinged at the rear and equipped with hydraulic pistons to lift the front, allowing the material in the bed to be deposited on the ground behind the truck at the site of delivery. By definition, this truck does not necessarily come equipped with a sealed tailgate. The roll-off and dump trucks will also be considered with and without a leak-proof liner, as some may not contain a sealed leak-proof tailgate.

Each of these types of trucks has certain advantages and disadvantages. The decision to utilize the standard rendering truck as the primary form of conveyance is based on industry standard practices and the availability of equipment in the event of a FMD outbreak with mass animal depopulation. The standard rendering truck, roll-off and dump truck will be considered both
with and without the following mitigations that can be used in conjunction with the trailer: 1) Tarp covering, and 2) Bio-Zip™, leak-proof carcass bags (Appendix B: Bio-Zip™ Bags product information). Bio-Zip™ liners can be used to manage large volume biological waste streams, leakage and environmental contamination issues. The bags are constructed of coated layers of polypropylene-based material fitted with an industrial grade zippered sealing system. The Bio-Zip™ material is 100% solids and contains no hazardous air pollutants. It has a zero rating for health, fire and reactivity and is zero class flammability. The Bio-Zip™ sealable liners fit securely inside industrial roll-off containers, trailers or truck racks from 10 to 40 cubic yards in total volume. Bags are placed in the trailer and filled on premises with infected carcasses. The entire bag is then removed from the trailer at the disposal site and disposed of. Bio-Zip™ bags meet US regulations for land fillable materials.

By determining the likelihood of leakage with the standard rendering truck and various mitigations, the assessment can be extrapolated to the other types of trucks with and without mitigations as well.

### 5.3. Transportation Regulations

Transportation of carcasses is well-regulated in federal, state and local jurisdictions. Although it can be inferred from rules and known standards for carcass transport, there are no specific governing regulations for movement of high numbers of carcasses, such as in a disease outbreak situation. For purposes of this risk assessment, the assumption is that all conveyance of carcasses during the depopulation procedure of a FMD infected premises will follow federal regulations for carcass movement (9 CFR 325.21, Code of Federal Regulations and Federal Register). This section states that “All vehicles and other means of conveyance used by persons subject to 9 CFR 325.20 for transporting in commerce or importing, any dead, dying, disabled, and diseased livestock or parts of carcasses of livestock that died otherwise than by slaughter shall be leak-proof and so constructed and equipped as to permit thorough cleaning and sanitizing.”

<table>
<thead>
<tr>
<th>Federal Regulation</th>
<th>Addresses</th>
</tr>
</thead>
<tbody>
<tr>
<td>9 CFR 325.21</td>
<td>Means of conveyance in which dead, dying, disabled, or diseased livestock and parts of carcasses thereof shall be transported.</td>
</tr>
<tr>
<td>9 CFR 325.20</td>
<td>Transportation and other transactions concerning dead, dying, disabled, or diseased livestock, and parts of carcasses of livestock that died otherwise than by slaughter.</td>
</tr>
</tbody>
</table>
For the case of a mass depopulation, we assume that the federal transportation regulations are followed as the minimum standard for all states. It is assumed that all rendering vehicles used in depopulation transportation efforts will be leak-proof. Rendering vehicles are required to be leak-proof but not airtight. States have additional regulations for carcass transportation that vary somewhat from state to state. Most states require that the carcass transportation trucks be licensed and permitted, and pass annual vehicle inspections. Some states also have specific requirements as to the timing of cleaning and disinfection of vehicles. This risk assessment assumes the state of origin of carcasses and state of disposal site carcass transportation and disposal statutes will be followed (Appendix C: Federal and State Regulations for Carcass Movement).

5.4. Pathway analysis for Carcass Movement

Figures 7 and 8 show the series of events and pathways by which susceptible species may be infected via the movement of FMD infected carcasses from an infected farm. Two main release and exposure pathways are assessed in the current risk assessment: 1) leakage of contaminated body fluids from the rendering truck and cross-contamination with other trucks, personnel or equipment that will be in contact with susceptible livestock in other uninfected farms (Figure 7 and Figure 8 A); 2) aerosolization of FMDv particles from the carcasses during movement and subsequent air transportation of those particles to uninfected farms with susceptible species (Figure 7 and Figure 8 B).

Figure 7: Series of events to expose susceptible species to FMDv through the movement of infected carcasses.
6. Hazard identification

6.1. Background

Foot and mouth disease (FMD) is a highly contagious viral disease affecting primarily cloven-hoofed animals. The disease is characterized by the development of vesicles in and around the mouth and on the feet. Although natural FMD infection rarely causes the death of mature animals, the disease results in decreases in livestock productivity and causes serious economic impact on international trade of animals and animal products (OIE Technical Disease Cards).

FMD was last reported in the U.S. in 1929 and in North America in 1952 (Canada) and 1954 (Mexico). As of May 2012, of the OIE’s 178 Member Countries, 102 do not have FMD-free status, 66 are recognized as officially free (65 without vaccination and one with vaccination), and ten have officially free zones (6 without vaccination and 4 having zones with or without...
vaccination). Out of the 102 countries without FMD-free status, 6 had an official status that is currently suspended (current FMD status can be found at www.oie.int.gov). There is substantial concern about incursions of this disease into the U.S., because of the unexpected occurrence of FMD outbreaks in previously FMD-free countries, including Taiwan (1997, 2000); Japan (2010, 2000); South Korea (2010, 2000, 2002); North Korea (2007); South Africa (2000, 2006, 2007); Argentina (2001, 2006); Russia (2006, 2007) and Europe (2001). The potential risks and impacts that FMD may pose were demonstrated by the severe economic and livestock losses experienced in the United Kingdom in 2001. The historical consequences of these FMD outbreaks has reinforced the need for FMD awareness and evaluation of the possible pathways by which FMDv can spread and infect livestock and contaminate food sources, and how these can serve as a further route for spread of the virus (USDA FAD PReP, 2013).

6.2. Virus Characteristics

There are seven FMDv serotypes: A, O, C, SAT 1, SAT 2, SAT 3 and Asia 1. Each serotype can be divided further into subtypes. Serotypes A, O, C, SAT1, SAT2, SAT3, and Asia1 contain 32, 11, 5, 3, 6, 3, and 4 subtypes, respectively. All serotypes produce disease that is clinically indistinguishable, but immunologically distinct. No cross-immunity is conferred between serotypes. Serotype O is the most prevalent and occurs in many parts of the world. Within each serotype is a spectrum of antigenic variation, resulting in strains having close or distant relationships to each other. Serotype A has the greatest antigenic variation ((Kitching RP, 1989); (Kitching RP, 1998); (Alexandersen S, 2005)).

6.3. Host range of FMD

Cloven-hoofed animals (ungulates) are the natural domestic and wild hosts of FMDv. They are susceptible to all 7 serotypes and many of the subtypes of FMDv. The severity of illness may differ depending on the specific serotype and the species that is affected. Susceptible species include cattle, pigs, sheep, goats, water buffalo, impala, bison, African buffalo, American Bison antelope, reindeer, moose, elk (although low), hedgehogs, porcupines, giraffes, elephants and Bactrian camels. Horses are resistant to FMD infection. New World camelids (llamas, alpacas, vicunas and guanacos) have low susceptibility to FMD infection. FMDv may also be transmitted to mice, rats, guinea-pigs, rabbits, hamsters, embryonating chicken eggs, chickens and various wild species, including European hedgehogs, chinchillas, muskrats, armadillos and peccaries. However, these latter species are not generally capable of spreading FMD (Alexandersen S, 2005).
Humans can become infected with FMD through (1) handling of diseased livestock with virus entry through skin wounds and mucous membranes, (2) exposure through laboratory situations, or (3) by drinking infected milk. The virus is not readily transmissible to humans and thus should not be considered a zoonotic disease. (OIE, 2008) Cases of human disease are rare and have resulted in temporary and mild signs of disease (fever, vesicles on the hands, feet or in the mouth) (Alexandersen S, 2005). In contrast, Hand, Foot, and Mouth disease (HFMD) in humans is an unrelated viral disease that primarily affects infants and children. The human disease is often confused with FMD of livestock.

### 6.4. Transmission

FMDv is highly contagious, and can be transmitted by a variety of mechanisms. When infected and susceptible animals are in close proximity, the airborne transfer of droplets is the most common mode of transmission. Other common mechanisms by which FMDv is spread are summarized below ((Alexandersen S, 2003b); (Alexandersen S, 2005)).

- Direct contact with infected animals and movement of animals between premises.
- Contact with secretions from shedding animals—exposure to secretions or mechanical transfer between groups by fomites (hands, footwear, clothing, vehicles, and equipment) and subsequent virus entry through cuts or abrasions in the skin or mucosa.
- Ingestion of FMDv contaminated animal products (meat) by pigs through swill feeding.
- Spread by wind, an uncommon event that requires the simultaneous occurrence of particular epidemiological and climatic conditions.

### 6.5. Incubation Period

The incubation period of an infectious disease is the time interval between exposure to an infective dose and development of clinical signs. The incubation period for FMD is known to be variable and dependent on the strain and dose of the virus, the route of transmission, the husbandry situation, and the species (Alexandersen S, 2003a). It is well known that FMD infected animals can shed virus during the incubation period, before the first detectable clinical signs are noted ((Orsel K, 2009); (Alexandersen S, 2001)). The peak of viremia can occur just before the animal breaks with clinical signs.

For control purposes, the OIE uses 14 days as the incubation period of FMD ((OIE, 2008); (Alexandersen S, 2003b)) summarized the variability observed in the incubation period of the disease, which is presented below:
• There is a strong inverse relationship between the dose of virus and the length of the incubation period, i.e., the higher the dose, the shorter the incubation period.
• The incubation period is usually 2-14 days, but can be as short as 24 hours.
• The latent period (animal exposed, infected and shedding the virus) is 1-2 days (Eble P, 2006).

6.6. Clinical Signs

Primary replication of FMDv takes place in the nasal and pharyngeal mucosa. Spread from these primary sites occurs to lymph nodes and the bloodstream, and resultant viremia distributes the virus to all organs and tissues. Viremia can commence a few hours after infection, and usually within 36 hours post-infection. Further replication of virus occurs in permissive cells and particularly at sites where characteristic lesions of FMD develop (Alexandersen S, 2001). The appearance of vesicles usually coincides with the peak of viremia and the highest concentration of virus is in tissues where the vesicles develop.

FMD in pigs is clinically indistinguishable from other viral vesicular diseases of swine (swine vesicular disease, vesicular stomatitis, vesicular exanthema) (Alexandersen S, 2001). It is usually severe and is characterized by lameness, reduced feed intake, lowered production, and the development of vesicles in and around the mouth and feet. Affected pigs become lethargic, remain huddled together and develop vesicles on the coronary band and heel of the feet, snout, lower jaw and tongue (Kitching RP, 2002). Body temperatures in pigs usually range from 39°C to 40°C, but can reach 42°C. The morbidity rate varies by the species affected, virus serotype and/or strain, and other factors. In regions where FMD is not endemic, the morbidity rate can be as high as 100 percent. The mortality rate is generally very low in adult animals, but may be high in young animals due to acute myocarditis (Alexandersen S, 2003b).

6.7. Concentration of virus in tissues, secretions, excretions

FMDv is present in multiple tissues, secretions and excretions of infected animals during pre-clinical, clinical, and post-clinical stages. Urine and feces contain virus but in low concentrations. Fresh feces collected from the floor have been found to contain small concentrations of the virus up to 10 days post infection in pigs (Parker J, 1971). The amount of aerosolized virus from infected animals can vary considerably. In contrast to other animals affected by FMD, infected pigs are recognized as the largest producers of aerosolized virus, excreting virus concentrations in the range of $10^{5.6}$ to $10^{8.6}$ TCID$_{50}$ per pig/day (Alexandersen S, 2005). Although pigs are large aerosol producers, they are very resistant to infection by this route. If a large group of pigs becomes infected with an appropriate viral serotype, the group can
excrete large volumes of aerosolized virus, which can be transported to farms downwind and constitute a risk to sheep and cattle. Ruminants excrete less virus in their breath ($10^4$ to $10^5$ TCID$_{50}$/day) compared to pigs, but are highly susceptible to infection via the inhalation route (Alexandersen S, 2005).

In comparison with other livestock species, cattle are the largest overall producers of FMDv from all secretions/body fluids combined and are probably the main source for environmental contamination. They produce large volumes of FMDv in the epithelium of the tongue, which often sloughs off during clinical disease, as well as in saliva, urine, feces and milk, in comparison to other species. Cattle are extremely susceptible to infection by aerosol exposure to virus due to their large respiratory volume and may become infected at concentrations of FMDv as low as 0.06 TCID$_{50}$ per cubic meter of air (Donaldson AI, 2001). Survival time of FMDv post-mortem depends on the stage of disease at the time of slaughter, the organs affected, and the strain of virus.

6.8. Environmental Persistence

FMDv retains infectivity for considerable periods of time in the environment, provided it is protected from desiccation, heat and adverse pH conditions. For example, the virus may survive for 14 days in dry fecal material; six months in slurry in winter; 39 days in urine; 28 days on the surface of soil in autumn; and three days on the surface of soil in summer. Such observations have generally been made in countries with a temperate climate, and these survival times can be expected to be much the same in hotter climates (Geering WA, 2002). FMDv is sensitive to desiccation. Relative humidity and temperature are the primary factors that affect survival of the virus in the environment. The virus survives best when the relative humidity exceeds 70%, and has poor survival when the relative humidity is below 50-60 (Sellers R, 1971). Sunlight and ultraviolet radiation have little effect on virus persistence (Donaldson AI, 1975).

7. Entry Assessment

The entry assessment comprises the risk associated with the release of FMDv during the movement of swine and cattle carcasses from FMD positive premises to the disposal site. The release could occur by cross-contamination via contaminated body fluids escaping from the disposal vehicle or by transmission of FMDv by aerosolization. Each of these events was characterized by a pathway and, for each of the pathways, the likelihood of occurrence was evaluated based on available scientific information, logical assumptions and input from experts.
The pathways considered in the entry assessment that would result in the release of FMDv through swine and cattle carcasses movement were the following:

- Likelihood that carcasses moved from FMD positive premises will contain an infective dose. In this pathway, a disease spread model for FMD in swine, dairy and beef cattle and expert opinion were used to estimate the total time from infection to depopulation, the number of viremic and recovered animals, and the FMDv concentration in carcasses to be moved after depopulation.
- Likelihood that transportation of carcasses will produce leakage and spillage of fluids contaminated with FMDv. In this pathway, body fluid capacity of swine, dairy and beef cattle was estimated. Characteristics of the disposal trucks were analyzed for the potential for leakage of body fluids.
- Likelihood that transportation of carcasses will produce aerosolization of FMDv. In this pathway, the potential for aerosolization of FMDv particles during movement of carcasses was evaluated by using expert opinion.

### 7.1. Likelihood that swine and cattle carcasses moved from a FMD positive premise will contain an infective dose

**Summary:** Time for FMD detection was estimated by a disease spread model to be between 4-10 days for swine and beef cattle and 3-9 days for dairy cattle premises at different sizes. Total time from infection to depopulation (including detection and confirmation) for the first FMD infected case was estimated to be between 10-15 days for swine, 8-12 days for dairy and 10-14 days for beef cattle premises. Total time estimated for subsequent FMD cases was between 7-12 days for swine, 6-9 for dairy and 8-11 days for beef cattle premises. Most of the animals (>65% for the first case and >81% for subsequent cases) will be viremic at the time of depopulation. The average concentration of FMDv in a carcass in experimental inoculation studies was $10^3$ PFU/g for a pig carcass and $10^6$ PFU/g for a cattle carcass. The total amount of infected carcasses moved to the disposal site was between 23-390 cattle carcasses and 117-780 pig carcasses per truck. This range was based on the weight of the animal carcass as well as the capacity of the truck trailer, taking into account the number of carcasses that could fit in the trailer. Any small amount of body fluids from the carcasses would contain virus that greatly exceeds the infective dose. 1 mL of body fluids could contain same amount and 10-100,000 times higher virus quantity ($10^3$-$10^6$ PFU) than the minimum infectious dose by oral ($1.4\times10^4$-$1.4\times10^6$ PFU) and inhalation route (7-357 PFU) for pigs and cattle. **Likelihood estimation:** The likelihood that the disposal truck with swine and cattle carcasses moved from FMD positive premises will contain an infective dose is high.
7.1.1. Time for FMD detection

The time for FMD detection was estimated by a stochastic disease spread model. The parameters used in the model for the simulation of disease spread within a group are presented in Table 5: Input parameters used in the FMD spread model in a swine farm. Estimates of animal level disease stage duration (latent, pre-clinical, clinical and recovery) were obtained from a recent study completed by USDA-APHIS-CEAH (USDA, 2012) by evaluating animal level data from published studies involving experimental infection with FMDv. The farm sizes selection was based on a compilation of statistics published by the National Agricultural Statistics Service (NASS) of the USDA for 2007-2012.

The surveillance component used in the model was based on observation of clinical signs and, using a conservative approach, was set at one time per day. The threshold for considering detection of the disease was set at 5% of the herd showing clinical signs. These values were based on expert opinion of subject matter experts regarding the average percentage of naturally occurring lameness on swine and cattle farms in the period of 2007 and 2009 ((USDA 2007); (USDA 2009)). The following components of the NAHMS survey were considered: the percentage of pig deaths from lameness (i.e. 5.4% for all group sizes); unusually high number of pigs unwilling to eat or stand up (i.e. 7.3% for all group sizes); and lame pigs with reddened areas above the hooves (i.e. 2.4% for all group sizes). Naturally occurring lameness is hard to predict, since it will be different from one producer to another, depending on the farm characteristics. Endemic lameness could mask the clinical signs of a FMD outbreak and has been reported to be less than 5% for cases of mild lameness and less than 0.5% for severe lameness (Dr. Peter Davies, personal communication).

The assumptions applied to the model included the following:

- The spread model does not include the aerosol route of infection or cross-contamination within groups (personnel and equipment), only direct contact between animals.
- The disease spread model assumes direct contact between all the animals in a herd, which may overestimate the number of infectious animals in large feedlots.
- The on-farm surveillance is based on daily visual observation for clinically suspicious animals. Clinically suspicious animals include animals with signs from any disease that is similar to FMD.
- Inputs for the analysis are based on published literature and the best current knowledge of the disease biology.

Appendix A: Model Disease Spread, contains the detailed information on the inputs and analysis of the model.

Percentages of farm sizes (100-50,000 head) for swine, dairy and beef cattle premises based on USDA NASS data for 2007-2012 was used to predict the most likely farm size where the occurrence of an FMD outbreak could happen. For example, for the swine industry the percentages of different farm sizes were as follows: 1-99 head (71.3%), 100-499 head (7.3%), 500-999 head (3.4%), 1,000-1,999 head (4.8%), 2,000-4,999 head (8.3%), and $\geq5,000$ head (4.8%). These data were included in a discrete distribution function to characterize the distribution of the swine farm sizes in the US by using @Risk software (Palisade Corp., Ithaca, NY, US) by the following distribution:

\[
\text{RiskDiscrete} \{100,500,1000,2000,5000,10000\}, \{0.713,0.073,0.034,0.048,0.083,0.048\} \quad \text{Eq. 1}
\]
In any given outbreak situation, there is a 95% chance that the outbreak occurs in a pig farm with 5,000 head or less, in a dairy farm with 500 head or less, and in a feedlot beef farm with 1,000 head or less. Time for disease detection will depend on the farm size and clinical observation and was estimated to be between 4-10 days for swine and 3-9 days for dairy and beef cattle premises.

7.1.2. Time from detection to depopulation

Time from detection to depopulation was estimated by adding the time for detection and the time for starting the depopulation with the following equation:

\[
\text{Total time} = t_{\text{det}} + t_{\text{conf}} + t_{\text{dep}}
\]

where \(t_{\text{det}}\) is the time for FMD detection depending on the farm size, \(t_{\text{conf}}\) is the time to the official laboratory confirmation of the disease and \(t_{\text{dep}}\) is the time to start the depopulation procedure.

Time values for disease confirmation, starting the depopulation and depopulation rates were obtained from experts from Texas A&M Transportation Institute, West Texas A&M, Department of Homeland Security and APHIS. Time values were characterized by a Pert distribution, and @Risk software was used to estimate the total time by using Monte Carlo simulation with 10,000 iterations. Input values for swine, dairy cattle and beef cattle premises are shown in Tables 9, 10 and 11, respectively. Total time from infection to depopulation for the first FMD infected case was estimated to be between 10-15 days for swine, 8-12 days for dairy and 10-14 days for beef cattle premises. Total time estimated for subsequent FMD cases was between 7-12 days for swine, 6-9 for dairy and 8-11 days for beef cattle premises (Table 7).

Depopulation times were estimated by the following equation:

\[
\text{Time for depopulation} = D_R \times \text{farm size}
\]

Eq. 3
where $D_R$ is the depopulation rate in heads/h and farm size is the amount of heads in a farm.

7.1.3. Number of viremic livestock after depopulation

The stochastic disease spread model was used to estimate the number of viremic (pre-clinical and clinical) and recovered animals at the time of depopulation for specific farm sizes (3,000 head for swine, 2,000 head for dairy and 5,000 head for feedlot cattle). Two different scenarios were evaluated: 1) First FMD case (Table 12); 2) Subsequent FMD cases (Table 13). The subsequent cases scenario was set at the minimum values obtained from experts for laboratory confirmation of the disease (24 h) and starting the depopulation procedure (24 h), due to the higher awareness of the disease. As shown in the table, most of the animals will be viremic (containing active FMDv) at the time of depopulation.

*: After 10,000 iterations (5<sup>th</sup> and 95<sup>th</sup> percentile values). Times are adjusted for each of the farm sizes. The time from detection to laboratory confirmation and from confirmation to starting the depopulation procedure was set at a total time of 48 h.

Figures 9, 10 and 11 show the disease spread curve within a swine, dairy and beef cattle population for the first index case. As shown in the figures below at the time of depopulation there will be 2,300 viremic pigs, 1,400 viremic dairy cows and 3,500 viremic beef cattle.
Figure 9: FMD curve in a 3,000 head swine farm during the first index case

Figure 10: FMD curve in a 2,000 head dairy cattle farm during the first index case
7.1.4. FMDv concentration in swine and cattle viremic carcasses

The concentration of FMDv observed in fresh tissues of pig skeletal muscle, fat, blood, lymph nodes and bone marrow in literature studies was from $6.31 \text{ PFU/g}$ to $10^{9.6} \text{ ID}_{50}/g$ for pigs (Table 14). It is worth noting the majority of reports were based on the ‘worst-case scenario’, where pigs were inoculated with high virus titers (Mebus C, 1997). The studies suggest that the greater quantities of virus were detected in pig blood, bone marrow or lymph nodes ((Alexandersen S, 2001); (Sellers R, 1971); (Chou CC, 2004); (Mebus CA, 1993); (Savi P, 1962)). The lowest quantities of virus were found in fat and muscle ((Mebus CA 1993); (Chou CC, 2004)). Given the high viral titers found in the various tissues, it is highly likely that FMDv would be present in the pig carcass tissues.

NP: None reported

ND*: None detected - The average titer of the sampled pigs was slightly greater than 0 PFU/g, with two samples with titers 10 PFU/g

**: Units not reported

TCID$_{50}$ (Median Tissue culture infectious dose) = The amount or quantity of a pathogenic agent (e.g. FMDv) required to produce a damaging effect to 50% of cells in the tissue inoculated.

PFU (Plaque forming units) = Provides an estimation of the number of infectious viral particles present by measuring the number of clear areas (areas of cell lysis) that are formed for a given culture plate area. One PFU equals about 1.4 TCID$_{50}$ for FMDv based on the equation by Horzinek (Horzinek MC, 1985).

Detectable viral titers in different cattle tissues ranged from $10^{2.5}$ PFU/g to $10^{10.6}$ PFU/g (Table 15). As was the case with swine, the majority of reports in cattle were based on the ‘worst-case scenario’, where cattle were inoculated with high virus titers. The studies suggest that the greater quantities of virus were detected in heart muscle, adrenal glands, pharynx and lymph nodes (Burrows R, 1966). The lowest quantities of virus were found in nervous tissue and spleen ((Scott FW, 1965); (Cottral GE, 1969)). Given the high viral titers found in these tissues, it is highly likely that FMDv would be present in cattle carcass tissues.

### 7.1.5 FMDv concentration in the disposal truck

Tables 16 and 17 show the weight ranges of different production phases and animal capacity at different size options for the standard rendering truck trailer. The concentration of the FMDv in
the disposal truck will depend on the number of viremic carcasses and the virus concentration per carcass. Table 17 shows that the total amount of FMDv contained in a 50000 lbs disposal truck is between $2 \times 10^{11}$ and $2 \times 10^{14}$ Plaque Forming Units. This FMDv concentration is 6-12 times higher than the minimum infectious dose for cattle, pig and sheep for the inhalation route. Any small amount of body fluids escaping the truck would contain enough quantity of virus to potentially infect susceptible population.

1: Doses are given as TCID_{50} (50% bovine thyroid tissue culture dose endpoint estimates).
2: One PFU equals about 1.4 TCID_{50} for FMDv.
7.2. Likelihood that transportation of carcasses will produce leakage and spillage of fluids contaminated with FMDv

Summary: The volume of body fluids of carcasses will vary depending on the growth phase, body weight and species. The time from depopulation to movement of carcasses to the disposal site will be very short (as a matter of hours), so the potential for body fluids to escape from carcasses (leachate) will be minimized. Mitigation measures such as sealed tailgate, tarp cover and the use of Bio-Zip™ bags will minimize the likelihood of leakage and spillage of carcass fluids from the disposal truck. Likelihood estimation: The likelihood of leakage and spillage of carcass fluids from a standard rendering truck (sealed tailgate and tarp cover) will be low. Adding a Bio-Zip™ bag will reduce the likelihood to between low and negligible for any type of truck. The rest of the scenarios (roll-off/dump trucks with/without tarp covering and liner) will have risk levels higher than low.

7.2.1. Carcass fluids

7.2.1.1. Leachate, Leakage and Spillage

Leachate is the liquid that is produced by the decomposition of livestock carcasses when water travels through a burial site and picks up products from decomposing carcasses and carries them through the soil. This is a process that follows euthanasia as the carcass starts to decompose. Through literature search and expert opinion, ranges of leachate production for livestock were quantified. Mammals are approximately 70% water and, as they decompose, they turn into a compost-like material capable of holding onto about 50% of that water (e.g., in a 50 lb. carcass, 17.5 lb. of body weight will be lost during the leachate process). Due to the short time elapsed between euthanasia and disposal, post-mortem autolysis will be minimal. Leachate as a potential contributor to spillage will, thus, not be considered further in this risk assessment. If time to disposal following euthanasia is extended, leachate may become more significant and warrant further consideration.

Leakage is the volume of liquid matter (including feces, urine, blood, ingesta, serum, saliva, etc.) that could be released from the carcass upon euthanasia, but is not part of the decomposition process. This can happen post-mortem through various means, such as loss of sphincter tone, through maneuvering of carcasses, and through the site of euthanasia (e.g. captive bolt entry point). Leakage is a factor that could facilitate the release of FMDv from the truck during movement. Spillage is when carcass fluid from leachate or leakage spills out from the conveyance source into the environment and could potentially contribute to the spread of FMDv.
7.2.1.2. Amount of Carcass Fluids

The table below summarizes the estimated body fluid volumes for cattle (both dairy and beef), as well as swine at different life stages. This is based on fluid volume comprising about 70% of total weight for most mammals. About two-thirds of these fluids are intracellular. So for example, based on total body fluids on a per weight basis, the volume range for potential leakage under worst case scenario for a calf (beef or dairy) would range from 6 to 20 liters. The volume of potential leakage from a nursery pig would range from 2 to 6 liters. These fluid quantities provide a reference for the total potential volume of leakage by weight and species. They are not considered an estimate of expected leakage.

7.2.2. Potential for Leakage and Spillage of Carcass Fluids during Movement

In consulting with rendering industry experts on the typical amounts of leakage from fresh, intact carcasses under normal conditions, the body fluids normally remain in the carcass. In a full load of a standard rendering truck (29–1000 carcasses), the amount of leakage that was estimated by expert opinion was around 20 liters per load. The table below summarizes the likelihood of leakage and spillage of carcass fluids from intact carcasses during transport, with or without...
further mitigation measures. The tarp covering will provide protection against aerosolization and spillage of carcass fluids, and the Bio-Zip™ bag will provide full protection for any of the possible pathways. The liner would provide a leak-proof barrier for fluids with a full-containment of carcasses and may aid in preventing spillage. It is not, however, sealed containment, such as with the sealed leak-proof tailgate or the Bio-Zip™ bag.

</tbody>
</table>

*: Capacity: 28', 32', 40'

From the table, it can be concluded that the use of a Bio-Zip™ bag, with any of the vehicle types, will produce a negligible to low risk of leakage and spillage of fluids during conveyance. The scenario of the standard rendering truck or roll-off and dump truck without tarp covering would have a moderate to high likelihood of spillage, due to the proximity of carcasses to the top of the trailer in a full load. Without mitigations to prevent spillage from the truck (i.e. tarp), carcass fluids may have the potential to escape.

7.3. Likelihood that transportation of carcasses will produce aerosolization of FMDv particles

Summary: Bioaerosol is a complex field of science where multiple parameters (e.g., environmental, climatic) can affect the survival and air transmission of FMDv. Likelihood estimation: The overall likelihood of bioaerosols emanating from a trailer and spreading infectious virus through carcass transportation activities is estimated as negligible to low if conveyance is in a standard rendering truck with tarp covering. If aerosols could be
produced from the carcass leakage, there is a moderate likelihood they could then move into the airstream.

7.3.1. Bioaerosol Science

Aerosols refer to an assortment of liquid or solid particles suspended in a gaseous medium (Gilbert Y 2009). Bioaerosols are aerosols that contain microorganisms, such as bacteria, fungi, and viruses—or organic compounds (endotoxins, metabolites, toxins, proteins from animals and plants, and other microbial fragments) (Macher J, 1999). The science of bioaerosols is extremely complex and requires an understanding of microbiology, biology, chemistry, meteorology, and aerosol physics (Mohr A, 2005). The sections below focus on the key points for general bioaerosol behavior that may pertain to FMDv associated bioaerosols. The ability to generate bioaerosols depends on the source, aerosolization mechanisms, environmental conditions, and composition (Pillai SD, 2002). Bioaerosols vary in size from 20 nm to >100 μm in diameter. Almost any environmental reservoir for microorganisms, such as fresh and marine surface waters, soil, plants, wastes and animals, is susceptible to being a source of bioaerosols.

Bioaerosols generated from water sources are generally surrounded by a thin layer of liquid that rapidly evaporates to give droplet nuclei. Droplet nuclei are the dried residue of larger aerosols that can remain airborne indefinitely on air currents. Transport of bioaerosols, and survival of airborne microorganisms, are influenced by many physical and environmental factors. The size, shape, and density of bioaerosols are of particular significance to transport because they are related to the aerodynamic diameter, which controls the settling velocity ((Cox C, 1995) (Mohr A, 2007)). Bioaerosols between 1 and 5 μm normally follow the pathlines of surrounding air, making them less susceptible than larger particles to impact surfaces and deposition (Mohr A, 2007).

7.3.2. Bioaerosols and FMDv

The airborne transmission of FMDv aerosols is complex. Windborne transport of virus can occur under specific epidemiological, climatic, and meteorological conditions, but is very uncommon. Prevailing climatic conditions, particularly wind speed and the vertical temperature structure, are major determinants of physical decay of aerosols. This is also influenced by the roughness of the surface over which the air plume travels. The survival of FMDv in plumes is likely across seaways, as the surface turbulence is low and concentrations of airborne particles can be maintained for greater distances than over land (Gloster J, 2005). The stability of FMDv is affected by radiation, RH, temperature, and weather factors. RH is the major meteorological
determinant affecting virus survival. It has been established that the virus is stable in aerosols at a RH above 60 percent and at temperatures below 33°C (91°F). Sunlight and a pollution complex termed “the outside air factor” have minimal direct effect on virus survival (Donaldson AI, 1975). The aerosols, once airborne, are subject to both physical and biological loss. Biologically, the virus may become inactivated if the RH of the air falls below 60 percent or the water vapor pH of the aerosol particle becomes acidic or alkaline (Gloster J, 2004). In the absence of turbulence, particles greater than 10 μm are likely to be removed from the atmosphere within minutes. Smaller particles may remain airborne for several hours and be carried many kilometers in the wind (Gloster J, 2007). Particles of 5 μm or less act as vapors and can move in and follow an airstream without impacting obstacles; this is the size of particle that represents the worst risk. It is unknown if bioaerosols from leakage of carcass fluids would require the same type of environmental conditions to remain viable and potentially lead to infection of susceptible livestock.

7.3.3. Expert Opinion on Bioaerosolization

There are no studies on carcass bioaerosols production in the literature. Bioaerosol science is a very complex field, and aerosol characteristics and behavior are measured quantitatively using sophisticated sampling methods and equipment. Questions on aerosol behavior cannot be accurately modeled mathematically, as it requires knowledge of the concentration of aerosols, the size distribution of aerosols, the media composition, and the environmental/atmospheric conditions under which they are generated. Due to the lack of information on carcass aerosols, the experts’ opinions and rationale were based on extrapolation of their knowledge in aerosol science. All of the experts agreed that experimentation is required to accurately answer these questions and to validate their opinions.

We queried three bioaerosol experts on the potential for generation of bioaerosols during transport and the expected behavior of the aerosols. The experts have different professional backgrounds and expertise within the field of aerosol science. The list of experts interviewed, the questions asked and a summary table of their answers are presented in Appendix G: Expert Opinion – Aerosols. Responses were compiled and compared for consensus between experts. The explanation of aerosol behavior varied slightly among experts, but the overall conclusions of the probability of occurrence of bioaerosols did not vary significantly. Expert opinion consensus was that the likelihood of aerosolization in an uncovered rendering vehicle during transportation was negligible to moderate. When the rendering vehicle was covered during transportation, expert opinion consensus was that the likelihood of aerosolization was negligible to low.

7.3.4. Potential for Aerosolization of Carcass Fluids during Movement

The likelihood estimate was based on the review of expert opinion, observation of truck design and operations, and current knowledge of FMDv epidemiology. The overall likelihood of bioaerosols emanating from a trailer with potential for spreading infectious virus through carcass transportation activities is estimated as low to moderate, if conveyance is in an uncovered standard rendering truck. When using a tarp covering, the likelihood was reduced to negligible-low, and with a Bio-Zip™ bag to negligible. In this case, if aerosols could be produced from the carcass leakage, there is a moderate to high likelihood they could then move into the airstream. Experts rated the likelihood of FMDv moving from the airstream into farms along the truck route as between moderate and high when trailer is uncovered, and between negligible to moderate when covered.

8. Exposure Assessment

The exposure assessment is an evaluation of the potential exposure pathways by which susceptible animals could be exposed to infectious amounts of FMDv. There are four major aspects of the exposure assessment: the exposed population, the pathway of exposure, the magnitude of exposure, and the likelihood of exposure. For the purpose of this assessment, the population of interest is primarily susceptible agriculture livestock species. The potential pathways for exposure are through the cross-contamination of trucks, personnel or equipment by FMDv contaminated carcass fluids, and exposure to aerosolized particles. These events and the factors associated with virus survival and infectiveness are uncertain.

For the exposure assessment of this risk assessment, the use of a standard rendering truck was assumed. In the entry assessment, the likelihood of the FMDv to be released during transportation was estimated to be between negligible to low (both for aerosolization and spillage). Based on the proposed mitigations in this assessment and the apparent effectiveness on the likelihood of virus to be released by the movement of carcasses, we conclude that the likelihood of exposure to FMDv by susceptible populations during the movement of infected carcasses will be negligible.

9. Risk Estimation

The risk of FMD infection of susceptible livestock associated with the movement of swine and cattle carcasses by leakage, spillage and aerosolization of carcass fluids will be negligible when using a standard rendering truck (tailgate sealed and tarp cover) and a Bio-Zip™ bag, between negligible and low when using a standard rendering truck or a roll-off/dump truck with a Bio-Zip™ bag. Other scenarios (uncovered standard rendering trucks, uncovered roll-off/dump trucks, covered roll-off/dump trucks and a liner) will have risk levels higher than low (moderate to high).

10. Conclusions

The following conclusions were drawn from this report:

- Conveyances evaluated will contain carcasses with a total FMDv amount that will exceed in several degrees of magnitude the minimum FMD infective dose for pigs and cattle.
The use of Bio-Zip™ bags is an effective mitigation to reduce the risk of leakage and aerosolization to negligible in standard rendering trucks and to low in the other conveyance types.

11. Recommendations for further research

An important goal of the risk assessment process is to inform the risk managers about the data gaps encountered during the production of the document and research strategies to fulfill the data gaps, in order to decrease the uncertainty in the risk estimation.

A review of the literature on FMDv in cattle and swine indicated the following data gaps, research needs and uncertainties:

1. The amount of virus that would be present in naturally infected animals and their tissues. It may be significantly lower than the doses that have been used in scientific research. Some variables that could be studied include: strains of FMDv, post-exposure intervals, age/size of pig/cattle.

2. Data on infectivity of waste materials (i.e. aerosols, liquids, and solids) generated during 3D operations (i.e. Depopulation, Disposal, and Decontamination).

3. Confirmation on how FMD infected carcasses will be classified for transportation purposes, especially under the circumstances of mass depopulation, with the possibility that infected carcasses could be designated with a different classification. In the case of a FMD outbreak, it is possible that the Federal HazMat Transport Regulations could be used to cover transportation. However, the Code of Federal Regulations 49 CFR Part 175 addresses the movement of test samples and vials, but not intact infected carcasses.

4. New modeling approaches that contain the aerosol route of infection or cross-contamination within groups (personnel and equipment) need to be explored.

5. Research on the aerosolization of FMD is limited or lacking. Expert opinion was used in this assessment, but targeted research would add additional data and confidence to the issue.
Acknowledgments
This project was developed in funded through a sub-award with West Texas A&M University through USDA-APHIS and DHS. We sincerely thank all those who contributed to the planning, writing, reviewing and expert opinion and contributed to the development of this risk assessment including: Kristen Johnson (University of Minnesota), Sasi Malladi (University of Minnesota), Dyan L. Pratt (University of Saskatchewan), Kristen Tom Beseman (Central Bi-Products) Thomas Kuehn and Peter Raynor (University of Minnesota), Shawn M. Guetter (Redwood Metal Works), Lori P. Miller (Department of Homeland Security), Robert E. De Otte Jr. and Donald Topliff, (West Texas A&M University), David Finch (Texas Animal Health Commission), Curtis Morgan (Texas A&M Transportation Institute), Michael Mays and Jimmy Tickel (North Carolina Department of Agriculture and Consumer Services), Darrel Styles (USDA APHIS), Peter Davies (University of Minnesota).

Appendix A: Model Disease Spread

This appendix provides additional information on the disease spread model used to simulate the spread of FMD within a swine and cattle group and estimate the number of pig and cows in various disease states at different time periods. The disease states included in the module are susceptible (S), latent (L), pre-clinically infected stage (I), clinically infected (C) and (R) (Carpenter, 2004). The module updates the number of pig/cows in the disease states at specific time steps (e.g., every 6 hours). The uncertainties in input variables as well as the inherent variability associated with FMD infection course in a pig/cow and spread within the group were considered in the model.

Assumptions and Notation

We have the following notation for this section:

- **N**: The number of pig/cows in the group.
- **i**: Index of pig/cows in the farm \( i \in 1, ..., N \)
- **t**: Index of time periods. \( t \in 1, ..., T \)
- **\( \hat{S}(t) \)**: Set of indices of pig/cows that are in a susceptible state in time period \( t \)
- **\( \hat{L}(t) \)**: Set of indices of pig/cows that are in a latent state in time period \( t \)
- **\( \hat{SI}(t) \)**: Set of indices of pig/cows that are in a pre-clinically infectious state in time period \( t \)
- **\( \hat{CI}(t) \)**: Set of indices of pig/cows that are in a clinically infectious state in time period \( t \)
- **\( \hat{R}(t) \)**: Set of indices of pig/cows that are in an immune state in time period \( t \).
- **\( P_R \)**: The probability that a pig/cow that is susceptible in period \( t \) becomes infected with FMD by period \( t+1 \).
- **\( N_i(t) \)**: The number of infectious pig/cows/cows/cows in time period \( t \).

- **\( K \)**: The adequate contact rate is defined as the expected number of contacts that a pig/cow has with other pigs/cows in a time period that are adequate to transmit FMD infection.

- **\( I^\text{new}_{t,t+1} \)**: The number of newly infected pig/cows between period \( t \) and \( t+1 \).

- **\( N_S(t) \)**: The number of susceptible pig/cows in period \( t \).
- **\( \tau^L(i) \)**: A model variable denoting the length of the latently infected period for a pig/cow in a specific simulation iteration. This parameter was simulated using an exponential distribution as detailed in section 9.3.
- **\( \tau^{SI}(i) \)**: A model variable denoting the length of the pre-clinically infectious period for a pig/cow/cow in a specific simulation iteration. This parameter was simulated using a lognormal distribution as detailed in section 9.3.
\( \tau^{CI}(i) \) - A model variable denoting the length of the clinically infectious period for a pig/cow/cow in a specific simulation iteration. This parameter was simulated using a gamma distribution as detailed in section 9.3.

\( T^L(i) \) - A model variable denoting the simulation time at which a pig/cow/cow \( i \) entered into latently infected state.

\( T^{SI}(i) \) - A model variable denoting the simulation time at which a pig/cow/cow \( i \) entered into pre clinically infectious state.

\( T^{CI}(i) \) - A model variable denoting the simulation time at which a pig/cow/cow \( i \) entered into clinically infectious state.

\( \lambda \) - The number of hours represented by each time period \( t \) of the simulation model. \( \lambda \) was set at 6 hours in our simulations.

The main assumptions associated with this model are listed below:

- The pig/cows that are in susceptible state in a time period, all have an identical probability of becoming infected by the next period, (i.e., differences in transmission due to grouping of pig/cows in pens are not considered).
- Pre-clinically infectious or clinically infectious pig/cows are both equally infective with respect to transmitting FMD, if they have an adequate contact with a susceptible pig/cow.
- The number of adequate contacts per pig/cow in a period follows the Poisson distribution.
- The variability in adequate contact rate due to differences in density of pig/cows (number of pig or cows per unit area) among different swine or cattle operations is not considered (i.e., the transmission is modeled as being frequency dependent).
- The clinically immune state is not considered in the model.

**The Transmission Equation**

The transmission equation estimates the number of susceptible pig/cows that become newly infected with FMD in each time period. The transmission equation is based on calculation of the probability that a susceptible pig/cow has an adequate contact with at least one infected pig/cow in a time period. The variables considered in the equation include the adequate contact rate, the number of infectious pig/cows, the number of susceptible pig/cows and the total number of pig/cows in the farm. In general, a higher adequate contact rate or higher proportion of infectious pig/cows will lead to increased transmission. We use the transmission equation derived in Dietz and Schenzle (Dietz K, 1985) as shown in Equation 1. This transmission equation assumes that the number of adequate contacts each pig/cow has in a period is Poisson distributed with a mean \((k)\). A Poisson process indicates a continuous and constant opportunity for an event to occur.

\[
P_t = 1 - e^{-\frac{k(N_i(t))}{N-1}}
\]

\[
f^{new}_{t,t+1} \sim \text{Binomial}(S, P_t)
\]

**Transition between Different Disease States**
The transmission equation provides the basis for calculating the number of pigs/cows transitioning from susceptible to the latently infected state in one time period. In this section, we briefly describe the implementation details for transitions between other disease states. As stated earlier, the model updates the disease states of the pig/cows in unit time steps (e.g., 6 hours). The transitions from latently infected to pre-clinically infectious, pre-clinically infectious to clinically infectious and from clinically infectious to recovered are based on keeping track of each individual pig/cow’s length of each disease state and timing of when a pig/cow transitioned into a disease state. For instance, in the case of transitioning between the latent to preclinical infected state for a pig/cow, the model first calculates the length of the latent period for the pig/cow ($\tau^L$) based on the latent time distribution. The model also keeps tracks of the time period when a pig/cow transitioned into the latently infected state ($T^L$). The model transitions the pig/cow from the latently infected to sub-clinically infected state in the first time period $t$ where $t^*\lambda \geq \tau^L + T^L$. Other disease state transitions are performed in a similar manner. The main input parameters for this section of the model are the probability distributions of latent, sub-clinically infectious and clinically infectious time periods. The model can be run for a specified number of time periods and provides the estimates of number of pig/cows in various disease states.
Product Description

The BIO-ZIP™ SEALABLE LINER is a cleaner way of managing large volume biological waste streams and potential odor, leakage, disease, and environmental contamination issues. Constructed using proprietary coated layers of polypropylene-based material also featuring an industrial grade zippered sealing system, the BIO-ZIP™ Sealable Liner fits securely inside industrial roll-off containers, trailers or truck racks from 10 to 40 cubic yards in total volume. It's easy to install, capable of containing large, heavy loads and will slips right out when it's time. ONE SIZE FITS ALL.

47-1209: Transportation of carcasses of domestic animals and packing house refuse; conditions and limitations.

All vehicles used in the transportation upon public highways of the carcasses of any domestic animals or packinghouse refuse, shall conform with the following conditions and limitations:

1. The carcasses of dead animals or packinghouse refuse, shall be placed in containers or vehicles which are constructed of, or lined with, impervious material, and which do not permit the escape of any liquid

2. after original loading, the carcasses of domestic animals shall not be moved from the transporting container or vehicle upon a public highway or in any other place except at the disposal plant, at an authorized substation, or at an authorized place for transfer of carcasses or refuse into line vehicles;

3. containers and vehicles shall be disinfected each time before leaving a disposal plant, or substation, and the exterior thereof shall be disinfected each time after loading and before entering the public highway, all in conformance with requirements and regulations prescribed by the commissioner;

4. containers and vehicles used for transporting of carcasses of animals or packinghouse refuse shall not be used for the transportation of live animals except to a licensed disposal plant or the transportation of food or feed for human or livestock consumption until properly cleaned and sterilized.

Wisconsin | [http://docs.legis.wisconsin.gov/statutes/statutes/95/50](http://docs.legis.wisconsin.gov/statutes/statutes/95/50) |

5.50 Transportation and disposal of animal carcasses.

2. Carcass transportation and disposal prohibitions. No person may do any of the following, either directly or through an employee or agent:

(a) Transport or dispose of a carcass that the person knows or reasonably should know to be a diseased carcass in a manner that creates a significant and foreseeable risk of transmitting disease to humans or animals.

(b) Dispose of a carcass in the waters of the state. This paragraph does not prohibit the use of farm-raised fish as bait.

4. Regulation of carcass transportation and disposal. The department may, by rule or order, regulate the transportation and disposal of carcasses to prevent and control contagious and infectious diseases.

5C-23.003 Transporting or Hauling Animal Carcasses or Refuse; Procedures; Records; Equipment; Quarantine.
Risk Assessment for the Transmission of Foot and Mouth Disease via Movement of Swine and Cattle Carcasses from FMD-infected Premises to a Disposal Site

(1) A copy of the official permit shall be kept in each vehicle used for transporting or hauling animal carcasses or refuse.

(2) Any person transporting or hauling animal carcasses or refuse shall keep records regarding the collection, transportation and distribution of animal carcasses or refuse. Such records must include the names and addresses of persons, firms and partnerships or corporations for which animal carcasses or refuse is being transported and cover the previous twelve months of operation.

(3) All vehicles and/or containers used to transport or haul animal carcasses or refuse shall be thoroughly cleaned and disinfected weekly or more often if deemed necessary by a representative of the Division. Each operator shall be responsible for the proper cleaning of his vehicles and/or containers.

(4) Vehicle and/or containers used to transport or haul animal carcasses or refuse which do not meet the requirement of this rule shall be placed under quarantine by the department until they are in compliance with this Chapter and proper cleaning and disinfection of the same has occurred.
Restrictions).

(h) Statewide application or part of state: The movement restrictions contained in this section can be made effective for all or part of the state in order to protect against exposure from a disease as identified in §58.2 of this title (relating to Disease Control).

<td>Disposal of Dead Animals and Rendering Plants 1719.0200 Permits. Subpart 1. Generally. Permits from the board are required for all trucks used to transport carcasses or discarded animal parts over public roads. The permit authorizes the permittee to transport the carcasses or discarded animal parts over public roads to an establishment but does not authorize crossing state lines. Permits are valid for one year unless revoked in accordance with Minnesota Statutes, section 35.93. The permittee shall comply with rules of other state and federal agencies. No permit is required for a person to haul the carcass of an animal which was owned by that person before the animal died. 1719.0310 Trucks crossing state lines. Trucks crossing state lines must meet applicable conditions in any reciprocal agreement between the states involved. 1719.0400 Truck owned by person other than owner or operator of rendering plant. If a truck is owned by a person other than the owner or operator of the establishment, the owner or operator of the truck and the owner or operator of the establishment are responsible for compliance with all laws and rules pertaining to the transportation of carcasses. The application must indicate the name and address of the owner of the truck. 1719.0500 Inspection of plant facilities and trucks. Subpart 1. Generally. Before permits are issued, an inspection of the plant, collecting station, and trucks must be made by an agent of the board to determine if the facilities of the plant and the trucks comply with this chapter. A report of the inspection must be filed with the board. Subp. 2. Repealed by amendment, 20 SR 2033</td>

<td><a href="http://legisweb.state.wy.us/statutes/titles/Title11/T11CH23AR3.htm">http://legisweb.state.wy.us/statutes/titles/Title11/T11CH23AR3.htm</a></td>
<td>ARTICLE 3 - TRANSPORTATION OF CARCASSES TO RENDERING PLANTS 11-23-301. Generally; exceptions. With the consent of the owner, unless removal is contrary to state, county or local sanitary regulations or in the opinion of the state veterinarian might result in spreading contagious or infectious disease or threaten the health of human beings, animals or poultry, carcasses of animals may be transported to any rendering plant legally operating without prior inspection for brands and ownership. The operator of a rendering plant within this state receiving the carcasses is a hide buyer and shall comply with W.S. 11-23-201 through 11-23-207.</td>
</tr>
</tbody>
</table>
Appendix D: Expert Opinion – Rendering

Expert opinion was sought on standard carcass transportation practices. Rendering companies have expertise in mass carcass removal and conveyance on a daily basis. Central Bi-Products, a full service rendering company that operates two complexes in Redwood Falls, MN and in Long Prairie, MN was contacted to provide expert opinion on carcass transportation in the rendering industry.

Expert opinion was sought on the means of conveyance (specifications, types of vehicles commonly utilized), standard procedures in carcass pick-up and transportation, and regulations regarding carcass conveyance.

The most commonly used trailers in the industry with the standard rendering truck (semi-truck with an open box container) are 28, 32 and 40 feet. Open containers are sealed with a tarp covering prior to transportation. These come in a variety of mechanisms. The majority of the industry in the Upper Midwest utilizes a roll-top system. Transportation regulations mandate that the rendering vehicles are leak-proof. In Minnesota, rendering vehicles are permitted and inspected. The driver can retrieve carcasses from locations without ever stepping foot on the premises using an automated grapple system on the standard rendering truck. Estimates on truck capacity for the maximum carcass weights of what each trailer can hold are below:

<table>
<thead>
<tr>
<th>Trailer Length (ft)</th>
<th>Trailer Weight Capacity lbs (kg)</th>
</tr>
</thead>
<tbody>
<tr>
<td>28'</td>
<td>40,000 lbs (18,182 kg)</td>
</tr>
<tr>
<td>32'</td>
<td>45,000 lbs (20,455 kg)</td>
</tr>
<tr>
<td>40'</td>
<td>50,000 lbs (22,727 kg)</td>
</tr>
</tbody>
</table>

According to the industry experts, in a full carcass load (cattle), the carcass fluid (manure, urine, blood, basically any liquid that can spill out of the carcasses and into the truck during transport process) depth that one typically would see in the bed of the rendering truck is very little if the animals are loaded fresh (within 24 hours). It was estimated that if one were to clean the bottom of the trailer with a broom and shovel you might get a 5 gallon pail full of carcass fluids, as there is very little leakage from fresh animals.
Appendix E: Expert Opinion – Depopulation

Sources and Generation

Expert opinion was sought for likely times for depopulation. Although official regulations state euthanasia and disposal will occur within 24hrs or as soon as possible after premises classification (Red Book, National Center for Animal Health Emergency Management, 2011), we know that these will be dependent on resources and scale of outbreak as well as interpretation. Experts in depopulation were contacted and requested to provide opinion on euthanasia time and depopulation rates.

Experts who agreed to provide opinions for euthanasia and depopulations times were:

- David Finch, Texas Animal Health Commission
- Lori Miller, Department of Homeland Security
- Donald Topliff, West Texas A&M University
- Jimmy Tickel, North Carolina Department of Agriculture and Consumer Services
- Darrel Styles, USDA APHIS

Euthanasia Time

The following questions were provided to experts. For each of these questions, experts were requested to provide their opinion on 1) minimum, 2) most likely, and 3) maximum timing.

1. What is the most likely time to start of euthanasia for FMD Index premises?
2. What is the most likely time to start of euthanasia for Subsequent FMD premises?
3. What are the most likely depopulation rates (Expert Opinion) for cattle and hogs. (animals /day or animals /hr)?
Appendix F: Aerosol Science

Sources and Generation

Generation of bioaerosols can occur under natural conditions as well as from human activities such as spreading of slurries, pressurized spray irrigation, and aeration basins at wastewater treatment plants. In general, airborne microorganisms (bacteria, fungi, and viruses), and their components, are generated as a mixture of droplets or particles, having different aerodynamic diameters ranging from 0.5 to 100 µm ((Cox C, 1995); (Lighthart B, 1994)).

Microorganisms associated with droplets evaporate to dryness or near-dryness before impacting the ground or vegetation and are transported by air currents (Dungan RS, 2010). The optimum aerodynamic particle range which represents a hazard to the human respiratory tract is between 1.0 and 10 µm ((Mohr A, 2005); (Mohr A, 2007)).

The dissemination and transport of bioaerosols depends on the method of bioaerosol generation and energy input into the system. Pressurized air, electricity, centrifugal forces, impaction, or heat can provide the energy needed to produce small particles. Many of these forces are so violent that inactivation of the microorganisms will occur. Fluids associated with newly aerosolized particles will instantaneously start to evaporate. The distribution and concentration of particle sizes are two important variables that directly affect the potential for dissemination and transport.

Transport

The transport, behavior, and deposition of bioaerosols are affected by their physical properties (i.e., size, shape, and density) and meteorological factors they encounter while airborne. Naturally occurring bioaerosols are ejected into the atmosphere by wind, rain and bursting bubbles, and other processes. The environmental conditions of wind velocity, RH, temperature, and precipitation significantly affect transport of bioaerosols with atmospheric stability being a major factor ((Jones AM, 2004); (Lighthart B, 2000)).

Bioaerosols are subject to inactivation and transport the moment they become airborne. Particle sizes of droplets are usually small (2 to 10 µm) and they tend to follow the streamlines of the local wind. Particles with sizes smaller than 5.0 µm act as vapors and follow the streamlines of the airstream. The aerodynamic diameter of particles determines whether it is small enough to follow the streamlines of the surrounding flows, or if it is large enough to cross streamline flow and impact upon a surface. Deposition of larger aerosols occurs through gravitational settling, impaction, diffusion, convection (due to temperature variations), and wash-out by raindrops (Muilenberg M, 1995).

Viability, Stability, and Infectivity
The viability of bioaerosols is dependent upon their chemical makeup and the environmental and meteorological factors they are exposed to, such as wind speed, temperature, and RH. These atmospheric conditions are strongly influenced by features such as large-scale flow fields, geographical locations, and local topography. The most significant environmental factors influencing viability are RH, solar irradiance, temperature, and oxygen concentration. Additional influences include air ions and open-air factors (OAF). Atmospheric turbulence is responsible for diffusion of particles during transport by the wind (mean wind speed) and is strongly influenced by local atmospheric conditions and the diurnal variation of solar irradiance reaching the ground.

Of all of the measurable meteorological parameters, RH is the most important with respect to aerosol stability, which is an important determinant of bioaerosol viability and infectiousness ((Mohr A, 2005); (Mohr A, 2007)). The majority of airborne microorganisms are immediately inactivated upon release because of environmental stresses (desiccation, temperature, and oxygen) which act upon and alter the surface of the microorganism. The fundamental factors that affect the viability of microorganisms are the state of the water and water content of the bioaerosol. As RH decreases, the water available to the exterior environment of the microorganism also decreases. Loss of water can cause dehydration, resulting in inactivation of many microorganisms. The RH of the system also directly affects the density of the bioaerosol unit. The size, shape, and density of the aerosolized particles are directly related to the aerodynamic diameter, which determines settling velocity and location of deposition in the respiratory tract ((Mohr A, 2005); (Mohr A, 2007)).

Studies to determine the effect of temperature on the fate of bioaerosols have generally shown that increasing temperatures tend to decrease the viability of airborne microorganisms (Dimmock NJ, 1967). It is difficult to separate the effects of temperature and RH, as the vapor pressure and RH of a system are dependent on temperature. The lipid content of the outer coat, or capsid of a virus, determines the stability at high or low RH values.
Appendix G: Expert Opinion – Aerosols

Bioaerosol Experts Interviewed and Questions
The three experts who responded to a request for expert opinion were interviewed about the probability of generating bioaerosols during pumping and transport of FMD-infected carcasses. Background information was provided to the experts on truck design, mitigations, and regulations. The following experts that agreed to an interview have varying backgrounds in aerosol/bioaerosols research including engineering and aerosol physics:

- Robert DeOtte, PhD, PE, PG, Professor of Civil & Environmental Engineering, West Texas A&M University
- Thomas Kuehn, MS, PhD, Professor, University of Minnesota, Department of Mechanical Engineering
- Peter Raynor, MS, PhD, Associate Professor, University of Minnesota, Division of Environmental Health Sciences

The questions below were posed to the experts in bioaerosol science. The table below summarizes their responses.

Expert opinion was sought as to whether or not infected fluids that may leak from the carcasses post-mortem (infectious fluids like feces, urine, stomach/rumen contents, blood, milk etc.) would generate aerosols while being transported from site of euthanasia to disposal. The conveyance assessed were a box trailer that is 1) open on the top and 2) one that is covered with a tarp.

Based on the likelihood definitions below, please provide expert opinion on aerosolization in 1) uncovered and 2) covered standard rendering vehicle during transportation

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Descriptive Definition</th>

<td>Low</td>
<td>The event would be unlikely to occur</td>
</tr>
<tr>
<td>Negligible</td>
<td>The likelihood that the event will occur is insignificant, not worth considering</td>
</tr>
</tbody>
</table>

1. What is the likelihood (see chart) of significant aerosolization of carcasses fluids during transportation?
2. What is the likelihood that a significant portion of the aerosolized particles to be less than 10 µm in size?
3. If aerosols could be produced from the carcass leakage, what is the likelihood they could then move into the airstream at a subsequent farm?
4. Can you briefly describe your rationale for the selected likelihood levels?
## Summary 3 - Expert Opinion on Bioaerosols

<table>

<td></td>
</tr>
</tbody>
</table>
There could be two potential mechanisms for particle formation: (1) the sloshing of fluids back and forth against walls and surfaces which could form particles as the fluids impact, and (2) wind eddies forming drops along the surface of the fluids. Although the carcasses will limit the sloshing of the fluids and the access of strong eddies against the surface of the fluids, thus reducing the risk of generation, I still think the likelihood is Moderate. | The only aerosolization process considered is direct generation by the air stream when the trailer is in motion. Generating aerosol particles from wet liquids or material that is moist is nearly impossible without extremely large shear forces caused by high air velocities. The liquid viscosity also plays a role, the more viscous the liquid the more shear force is required and the less likely that particles will be generated. Dried material that was liquid at one time is also quite resistant to particle production. Dry loose dust could be aerosolized in an open trailer but I think the materials you are working with should be very resistant to this. Another scenario is dripping from the trailer onto the roadway. This potentially could generate aerosols directly at elevated speeds and perhaps the material deposited on a roadway could be aerosolized by passing vehicles. I think the potential for this scenario to generate particles is higher than simply looking at the air forces generated in an open trailer because the fluid is being dripped in the form of small droplets into a fast moving air stream. Nonetheless, I think the likelihood of this causing any secondary infection is quite remote | Generating aerosols from the liquid collecting at the bottom of a trailer is unlikely. The carcasses above that pool will hinder air flow and limit the shear necessary to generate droplets. A more likely possibility for the uncovered trailer is matter on the hide of the upper layer or two of animals breaking loose by mechanical means and being carried by air currents away from the vehicle. These solid particles could be fairly large but if so, will settle quickly. The particles could impact solid surfaces and break into smaller particles. The particles of concern would be dust from dried, crushed manure on the hide. These can easily be smaller than 10 µm. |
| **COVERED** | 
If some aerosol droplets are generated, a significant number could be smaller than 10 micrometers because the water portion of droplets will evaporate, potentially causing larger droplets to rapidly become smaller. | 
With the open top, I think there is a strong possibility for any aerosol droplets created to get into the air at a subsequent farm. Thus, I rate 1. c. High, although the overall likelihood of this outcome is only moderate because I think the risk of aerosols being produced in the first place is moderate. | - |
<p>| If aerosols could be produced from the carcass leakage, what is the likelihood they could then move into the airstream at a subsequent farm? | High | Moderate | - |</p>
<table>
<thead>
<tr>
<th>Question</th>
<th>Rating</th>
<th>Description</th>
<th>Rating</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>What is the likelihood of significant aerosolization of carcasses fluids during transportation?</td>
<td><strong>Low</strong></td>
<td>Formation of droplets by wind eddies is negligible here, although droplet formation by sloshing fluid impacting on surfaces is still possible. Thus, I give 2. a. the Low rating.</td>
<td><strong>Negligible</strong></td>
<td>Dripping could be an issue but direct aerosol production from under a covered load should be negligible.</td>
</tr>
<tr>
<td>What is the likelihood that a significant portion of the aerosolized particles to be less than 10 µm in size</td>
<td><strong>Low</strong></td>
<td>Because the trailer is covered, humidity inside the trailer is likely to be higher than if the trailer is uncovered, meaning that aerosol droplets are less able to evaporate than in 1. b. Thus, I have rated 2. b. as Low.</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>If aerosols could be produced from the carcass leakage, what is the likelihood they could then move into the airstream at a subsequent farm?</td>
<td><strong>Moderate</strong></td>
<td>The trailer is not air tight, so there is still a significant possibility that any droplets formed will be able to escape the trailer at a subsequent farm. However, it is certainly less likely than if the trailer was uncovered, so I rate 2. c. as Moderate as opposed to the rating of High for 1. c.</td>
