Salmonella on U.S. Swine Sites—Prevalence and Antimicrobial Susceptibility

Background

In 2006, there were 17,252 cases of laboratory-diagnosed foodborne illnesses attributed to 10 organisms under surveillance by the Centers for Disease Control and Prevention (CDC). Salmonella was the most common bacterial pathogen identified, accounting for 38.6 percent of the cases.1 In humans, Salmonella causes fever, abdominal cramping, and diarrhea. Severe cases can result in systemic infections and even death. In a CDC analysis of the impact of foodborne illnesses, nontyphoidal Salmonella accounted for 25.6 percent of hospitalizations and 30.6 percent of deaths due to known foodborne pathogens.2

Foodborne Salmonella infections have been attributed to raw, undercooked, or contaminated poultry and poultry products; eggs, meat, and meat products; dairy products; vegetables; and other agriculture sources.3

Salmonella organisms can be transmitted from pigs to humans through consumption of contaminated pork products and direct contact with infected animals.4 5 Pigs can shed Salmonella in their feces during all stages of pork production without showing any clinical symptoms. Shedding is also common during transportation and at lairage (holding pens) in slaughter houses. Clinical signs of salmonellosis in pigs include fever, diarrhea, anorexia, abortion, and decreased weight gain.6

Although over 2,500 serotypes of Salmonella have been identified, most laboratory-confirmed Salmonella infections in pigs are due to a small number of serotypes. Antimicrobial resistance is serotype dependent. Multidrug-resistant strains of Salmonella, such as S. Typhimurium, have been recognized for years as important swine and human pathogens and are of concern to both veterinary and public health officials.

Salmonella on U.S. swine sites

In 2006, the USDA’s National Animal Health Monitoring System (NAHMS) conducted a study on swine health and management practices from a random sample of swine production sites with 100 or more pigs in 17 States.* These States represented approximately 94 percent of U.S. pig inventory and 94 percent of U.S. pork producers with 100 or more pigs.

As part of Swine 2006, fecal samples were collected from different areas of pen floors on 135 sites. On each site, up to 60 fecal samples were collected from pens containing grower/finisher pigs and cultured for Salmonella. From September 5, 2006, through March 15, 2007, 7,788 samples were cultured for Salmonella.

Overall, at least one sample was found culture-positive for Salmonella on 52.6 percent of sites, 43.5 percent of barns, and 18.4 percent of pens. Of the fecal samples cultured, 564 (7.2 percent) were positive for Salmonella. From these samples, 584 isolates were recovered (20 samples had 2 isolates). Twenty-seven different serotypes were identified; however, 4 serotypes accounted for 70.5 percent of isolates (table 1).

* States
Arkansas, Colorado, Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Carolina, Ohio, Oklahoma, Pennsylvania, South Dakota, Texas, and Wisconsin.
The 584 *Salmonella* isolates were tested for resistance to a panel of 15 antimicrobial drugs.** Resistance break points used by the National Antimicrobial Resistance Monitoring System were used to classify isolates as susceptible, intermediate, or resistant.

The percentage of *Salmonella*-positive sites was higher in Swine 2006 (52.6 percent) than in the NAHMS Swine 1995 and Swine 2000 studies (38.2 and 32.8 percent of sites, respectively). A comparison of the ranking of frequently isolated serotypes in 1995, 2000, and 2006 is shown in table 2. Derby, Agona, and Typhimurium Copenhagen were the top three serotypes in all three studies.

**Antimicrobial susceptibility**

Table 3 shows that all isolates were susceptible to amikacin, ceftriaxone, ciprofloxacin, and naladixic acid. Resistance to tetracycline was most common (78.6 percent of *Salmonella* isolates), followed by resistance to sulfisoxazole (67.3 percent of isolates).

*Intermediate isolates were classified as not resistant.

Table 4 shows the multi-drug resistance of the 584 isolates tested. About 20 percent of *Salmonella* isolates were susceptible to all antimicrobial drugs tested. Overall, 79.6 percent of the isolates were resistant to at least one antimicrobial drug, 73.9 percent were resistant to more than one antimicrobial drug, and 8.7 percent were resistant to nine or more drugs.

*Intermediate isolates were classified as not resistant.

** Amikacin, amoxicillin/clavulanic acid, ampicillin, cefoxitin, ceftiofur, ceftriaxone, chloramphenicol, ciprofloxacin, gentamicin, kanamycin, naladixic acid, streptomycin, sulfisoxazole, tetracycline, and trimethoprim/sulfamethoxazole.
Conclusions

Although the prevalence of Salmonella in swine feces in the United States remains low (7.2 percent of fecal samples tested culture positive), 52.6 percent of sites had one or more positive fecal cultures. The top three Salmonella serotypes isolated from swine feces have remained the same since 1995. Overall, 85.1 percent of isolates were resistant to 5 or fewer antimicrobials. Over 20 percent were not resistant to any 15 antimicrobials evaluated.
