Glyphosate-Tolerant Alfalfa Events J101 and J163: Request for Nonregulated Status

**Draft Environmental Impact
Statement—November 2009**

Glyphosate-Tolerant Alfalfa Events J101 and J163: Request for Nonregulated Status

Draft Environmental Impact Statement— November 2009

Agency Contact:

Ms. Cindy Eck
Biotechnology Regulatory Services
U.S. Department of Agriculture
4700 River Road, Unit 147
Riverdale, MD 20737–1236

The U.S. Department of Agriculture (USDA) prohibits discrimination in all its programs and activities on the basis of race, color, national origin, sex, religion, age, disability, political beliefs, sexual orientation, or marital or family status. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means for communication of program information (Braille, large print, audiotape, etc.) should contact USDA'S TARGET Center at (202) 720–2600 (voice and TDD).

To file a complaint of discrimination, write USDA, Director, Office of Civil Rights, Room 326–W, Whitten Building, 1400 Independence Avenue, SW, Washington, DC 20250–9410 or call (202) 720–5964 (voice and TDD). USDA is an equal opportunity provider and employer.

Mention of companies or commercial products in this report does not imply recommendation or endorsement by the U.S. Department of Agriculture over others not mentioned. USDA neither guarantees nor warrants the standard of any product mentioned. Product names are mentioned solely to report factually on available data and to provide specific information.

This publication reports research involving pesticides. All uses of pesticides must be registered by appropriate State or Federal agencies before they can be recommended.

CAUTION: Pesticides can be injurious to humans, domestic animals, desirable plants, and fish or other wildlife—if they are not handled or applied properly. Use all pesticides selectively and carefully. Follow recommended practices for the disposal of surplus pesticides and pesticide containers.

Table of Contents

Executive Summary	xiii
I. Purpose and Need	1
A. Introduction	1
B. Regulatory Authority	1
1. USDA	2
2. FDA	2
3. EPA	3
C. Glyphosate-Tolerant Alfalfa	3
1. National Environmental Policy Act Processes	4
2. Requirements for Further Environmental Analysis	10
II. Alternatives	11
A. Introduction	11
B. Description of Alternatives	11
1. No Action	12
2. Determination that J101 and J163 Alfalfa Plants are No Longer Regulated Articles, In Whole (Preferred Alternative)	13
C. Alternatives Rejected from Further Consideration	14
1. Prohibit Glyphosate-Tolerant Alfalfa	14
2. Impose Isolation Distances	14
3. Impose Geographic Restrictions	15
4. Impose Testing Requirement	15
III. Affected Environment	17
A. Overview of Alfalfa	17
1. Uses of Alfalfa	17
2. Biology of Conventional Alfalfa	18
3. Feral Alfalfa	21
B. Biological Environment at Risk	23
1. Glyphosate	24
2. Toxicology and Environmental Risk	26
3. Gene Flow	30
4. Alfalfa Consumption by Livestock	33
C. Socioeconomics	33
1. Domestic Economic Environment at Risk – Conventional Alfalfa	33
2. Domestic Economic Environment at Risk – Organic Alfalfa	48
3. Trade Economics of Conventional and Organic Alfalfa	53
4. Social Environment at Risk	55
D. Human Health and Safety	61
1. Risk from Gene Product	61
2. Risk from Glyphosate and Other Herbicide Use	61

E.	Land Use and Production Practices	67
1.	Alfalfa Production Practices	67
2.	Alfalfa Farming Practices	71
3.	Weeds in Alfalfa.....	73
4.	Crop Rotation in Alfalfa	78
5.	Regional Differences in Production Practices	78
6.	Distribution and Acreage (by State and County).....	84
F.	Physical Environment	89
1.	Soils.....	89
2.	Climate and Air Quality.....	89
3.	Water.....	90
IV.	Environmental Consequences.....	91
A.	Methodologies and Assumptions Used in Analysis	91
1.	Models, Risk Assessment, Cause and Effect	91
2.	Assumptions.....	92
B.	Plant Genetics and Gene Flow	93
1.	Gene Flow Due to Pollen Transfer and Pollination	93
2.	Gene Flow Due to Secondary Seedlings	96
3.	Seed Purity	96
4.	Gene Flow to Other Alfalfa Crops and Wild Relatives	98
5.	Weediness and Increased Glyphosate Resistance.....	105
C.	Biological Impacts	114
1.	Impacts to T&E Species from GT alfalfa J101 and J163 Gene Product	114
2.	Impacts to T&E Species from Herbicide Application.....	116
3.	Glyphosate and Other Herbicide Use and Comparative Toxicity...	120
4.	Impacts on Plants.....	122
5.	Impacts on Animals	123
D.	Socioeconomic Impacts on Domestic Non-GT Alfalfa Markets	125
1.	Conventional Alfalfa Hay Farming.....	125
2.	Impacts on Domestic Organic Alfalfa Markets	132
3.	Impacts on Dairy and Beef Markets	140
4.	Impacts on Trade.....	141
5.	Social Impacts	143
E.	Human Health and Safety Impacts	145
1.	Introduction of Gene Product into Foods	145
2.	Impact of Introduction of Gene Product into Animal Feed	146
3.	Glyphosate Exposure	147
4.	Consumption of GT Alfalfa Events J101 and J163	154
5.	Impacts from Changes in Production Practices to Human Health and Safety	155
F.	Land Use and Production Practices	155
1.	Implications for Cultivation Practices.....	155

G. Physical Environment	157
1. Impacts on Soils	157
2. Impacts on Climate and Air Quality	158
3. Impacts on Water and Water Use	159
H. Mitigation Measures	161
1. Introduction to Mitigation Measures	161
2. Mitigation Measures by Resource Area	162
I. Other Impacts.....	164
1. Unavoidable Impacts.....	164
2. Short-Term Versus Long-Term Productivity.....	164
3. Irreversible Commitment of Resources	165
4. Cumulative Impacts	166
5. Analysis of Cumulative Impacts by Resource Area	167
6. Summary	186
7. Compliance with Statutes, Executive Orders and Regulations	190

Appendices

A. List of Preparers	A-1
B. Public Scoping Comments	B-1
C. Distribution Lists	C-1
D. References	D-1
E. Acronyms and Glossary	E-1
F. Index.....	F-1
G. Effects of Glyphosate-Resistant Weeds in Agricultural Systems....	G-1
H. Effects of Glyphosate-Resistant Weeds in Non-Agricultural Ecosystems	H-1
I. The Potential for Gene Flow from Glyphosate-Tolerant Alfalfa (<i>Medicago sativa</i> L.) to Related Species.....	I-1
J. Effects of Changes in Farming Practices on Water, Soil and Air Due to Use of Glyphosate-Tolerant Alfalfa.....	J-1
K. Changes in the Economics of Alfalfa Farming with Deregulation of Glyphosate-Tolerant Alfalfa.....	K-1
L. Health and Safety Risks from Increased Glyphosate and Other Chemical Usage on Humans (Exclusive of Field Workers)	L-1
M. Health and Safety Risks for Field Workers	M-1
N. Potential Impacts to Wildlife, Amphibians, Plants, and Ecosystems from Increased Glyphosate and Other Chemical Usage	N-1
O. Colony Collapse Disorder and Glyphosate-Tolerant Alfalfa.....	O-1
P. FDA Submission.....	P-1
Q. Presence of Glyphosate-Tolerant Alfalfa in Human Food and Animal Feed	Q-1

R. Impacts to United States Trade of Deregulation of Glyphosate-Tolerant Alfalfa	R-1
S. Economic and Social Impacts to Conventional and Organic Farmers of Deregulation of Glyphosate-Tolerant Alfalfa.....	S-1
T. Downstream Effects to Organic Production and Marketing of Deregulation of Glyphosate-Tolerant Alfalfa	T-1
U. Character and Quality of Glyphosate-Tolerant Alfalfa Traits	U-1
V. Impacts of Roundup Ready Alfalfa on Production Practices and Marketing of Alfalfa Seed and Hay.....	V-1
W. Plant Pest Risk Assessment	W-1

Tables

3-1. End Use Products Approved for Use on Glyphosate-Tolerant Alfalfa	25
3-2. Application Rates of EUPs Recommended for Use on Glyphosate-Tolerant Alfalfa	26
3-3. Members of the Genus <i>Medicago</i> Found in North America as Listed by Nature Serve Explorer.....	31
3-4. Establishment and Production Cost of Conventional Alfalfa – Units Per Acre.....	36
3-5. Total U.S. Alfalfa Hay Acres and Value by Method of Production Practice (2002-2005).....	37
3-6. Domestic Alfalfa Hay Market (1,000s of Dollars).....	39
3-7. Price Differences of Hay Qualities (\$/Ton), 10-Year Average 1997-2006.....	41
3-8. Weight of Feed Costs in Dairy Farms.....	42
3-9. State Production of Alfalfa Seed (2007 Census of Agriculture)....	44
3-10. Alfalfa Seed Production Costs.....	46
3-11. Domestic Alfalfa Seed Market (1, 000s of Dollars).....	46
3-12. Organic Alfalfa Hay Harvested Acreage.....	48
3-13. U.S. Alfalfa Hay (Dry) Acreage, Ranked by Number of Certified Organic Acres by State, 2005.....	50
3-14. Alfalfa and Other Hay Exports from California, Oregon and Washington Ports (Tons), 2006.....	54
3-15. U.S. Forage Export Markets (1000s of Metric Tons).....	55
3-16. U.S. Organic Food Sales and Sales Growth Forecasts.....	57
3-17. Calculated EIQs for Alfalfa-Related Herbicides.....	67
3-18. Glyphosate-Resistant Weed Infestations by State.....	76
3-19. Recommended Rotations for Pest Reduction.....	78
3-20. Alfalfa Forage and Seed Production by State.....	80
3-21. Alfalfa Growing Regions and Percentage of Dry Hay Harvest by State.....	85
3-22. Alfalfa Dry Hay Harvest 2007 Census of Agriculture.....	87
4-1. Pollinator Foraging Distance.....	95
4-2. Seed Purity Standards by State.....	97

4-3.	Relative Potential for Gene Flow Between Populations of Alfalfa (Requires that Viable Seed is Produced).....	101
4-4.	Comparative Variety Trial Yield Results.....	126
4-5.	Cost Scenarios for GT Alfalfa.....	128
4-6.	Chronic Dermal HQs for General Worker Exposure Scenarios..	149
4-7.	Acute Dermal HQs for General Worker Exposure Scenarios.....	149
4-8.	Acute HQs by Age Group and Scenario.....	151
4-9.	Chronic HQs by Age Group and Scenario.....	151
G-1.	Herbicides Used in Conventional Alfalfa Farming	G-8
G-2.	Recommended Rotations for Pest Reduction.....	G-11
G-3.	Winter Survival Ratings.....	G-13
G-4.	Fall Dormancy Ratings.....	G-13
G-5.	Alfalfa Growing Regions and Percentage of Dry Hay Harvest by State.....	G-14
G-6.	Alfalfa Dry Hay Harvest 2007 U.S. Agricultural Census	G-15
G-7.	Glyphosate Resistant Weeds.....	G-23
G-8.	Glyphosate Resistant Weed Infestations by State.....	G-33
G-9.	Weeds in Alfalfa	G-58

Executive Summary

APHIS is proposing to grant nonregulated status to genetically-engineered glyphosate-tolerant alfalfa lines J101 and J163 based on the agency's analysis and conclusions that these genetically-engineered alfalfa lines are unlikely to pose plant pest risks. Additionally, APHIS has preliminarily concluded in this Draft Environmental Impact Statement (DEIS) that granting nonregulated status to glyphosate-tolerant (GT) alfalfa lines J101 and J163 will not result in significant impacts to the human environment.

Purpose and Need

"Protecting American agriculture" is the basic charge of the U.S. Department of Agriculture's (USDA) Animal and Plant Health Inspection Service (APHIS). APHIS provides leadership in ensuring the health and care of plants and animals. By ensuring plant and animal health, the agency improves agricultural productivity and competitiveness, and contributes to the national economy and the public health. USDA asserts that all methods of agricultural production (conventional, organic, or the use of genetically engineered varieties) can provide benefits to the environment, consumers, and farm income, and they can and should "coexist." The APHIS Biotechnology Regulatory Service's (BRS) mission is to protect America's agriculture and environment using a dynamic and science-based regulatory framework that allows for the safe development and use of genetically engineered organisms.

The regulations in 7 CFR part 340, "Introduction of Organisms and Products Altered or Produced Through Genetic Engineering Which Are Plant Pests or Which There Is Reason to Believe Are Plant Pests," regulate, among other things, the introduction (importation, interstate movement, or release into the environment) of organisms and products altered or produced through genetic engineering that are plant pests or that there is reason to believe are plant pests. Such genetically engineered organisms and products are considered "regulated articles." The regulations in § 340.6(a) provide that any person may submit a petition to APHIS seeking a determination that an article does not pose a plant pest risk and should therefore not be regulated under 7 CFR part 340. Paragraphs (b) and (c) of § 340.6 describe the form that a petition for a determination of nonregulated status must take and the information that must be included in the petition.

Background

On April 16, 2004, APHIS received a petition from Monsanto Company and Forage Genetics International (Monsanto and FGI), requesting a determination of nonregulated status under 7 CFR part 340 for two alfalfa

lines designated as J101 and J163, which have been genetically engineered for tolerance to the herbicide glyphosate.

APHIS evaluated the plant pest risks posed by the use of lines J101 and J163 and prepared an environmental assessment (EA) to identify and evaluate any environmental impacts resulting from the approval of the deregulation petition. In a notice published in the Federal Register on June 27, 2005 (70 FR 36917-36919, Docket No. 04-085-3), APHIS advised the public of its determination, effective June 14, 2005, that the Monsanto and FGI GT alfalfa lines J101 and J163 did not pose a plant pest risk and were therefore no longer considered regulated articles under 7 CFR part 340.

Approximately 9 months later, a group of organic alfalfa growers and several other associations filed a lawsuit in the United States District Court for the Northern District of California that challenged APHIS' decision to grant nonregulated status to J101 and J163. On February 13, 2007 the Court ruled that APHIS' EA failed to adequately consider certain environmental and economic impacts as required by the National Environmental Policy Act (NEPA), and the Court vacated APHIS' decision to grant nonregulated status to J101 and J163. The Court also ordered APHIS to prepare a NEPA-compliant environmental impact statement (EIS) before deciding whether to grant nonregulated status to J101 and J163. On March 23, 2007, APHIS published a notice in the *Federal Register* (72 FR 13735-13736 APHIS Docket No. 04-085-1) announcing the Court's decision that Monsanto and FGI GT alfalfa lines J101 and J163 were once again regulated articles under 7 CFR part 340. The GT alfalfa seed sales and planting that took place after the June 2005 deregulation decision were halted.

Once the GT alfalfa lines were deregulated in June 2005, those GT alfalfa lines' seeds were sold and plantings were started. In the two growing seasons (2005 and 2006) that GT alfalfa was on the market, ~200,000 total acres were planted in 1,552 counties and 48 States with the exception of Alaska and Hawaii. These GT alfalfa fields are still permitted to be harvested pursuant to the court order and have court ordered stewardship practices to minimize any potential of GT alfalfa being present in harvests of non-GT alfalfa harvests. APHIS prepared this draft EIS in connection with the order by the United States District Court for the Northern District of California that vacated determined the deregulated status of J101 and J163 alfalfa.

Alternatives and Affected Environment

In a Notice of Intent published on January 7, 2008, APHIS suggested three alternatives for evaluation. APHIS has removed from consideration the

concept of approving only one of the GT alfalfa lines (either J101 or J163) and not both lines because APHIS' plant pest risk assessment concluded that GT alfalfa lines J101 and J163 are unlikely to pose a plant pest risk. Since neither line poses a plant pest risk, both lines must be deregulated. Additionally, none of the comments received during the public comment period of the original EA in 2005 and during the public comment period of the NOI cited concerns regarding a difference in or occurrence of any plant pest risks in GT alfalfa lines J101 and J163. APHIS also removed from consideration the concept of approving GT alfalfa lines based on geographical restrictions, because both GT alfalfa lines are unlikely to pose plant pest risks, and there would be no regulatory basis for imposing restrictions in certain geographical areas.

Therefore, this document considered two of the alternatives described in the Notice of Intent: to grant nonregulated status to GT alfalfa lines J101 and J163 (preferred alternative), or to maintain the status of GT alfalfa lines J101 and J163 as regulated articles. Alternatives were analyzed with regard to their potential impacts on gene flow between GT alfalfa and non-GT alfalfa, weed development, wildlife species, special status species, herbicide use, plant species, socioeconomics (including conventional and organic alfalfa markets, dairy and beef markets, and trade), human health and safety, land use and production practices, and the physical environment (including soil, climate and air quality, and water).

Environmental Consequences

Based on the impact analyses in this DEIS, APHIS has preliminarily concluded that there is no significant impact on the human environment due to granting nonregulated status to GT alfalfa lines J101 and J163.

Summary of Environmental Consequences

Biology of Alfalfa

- Movement of genes between alfalfa plants is dependent on weather, timing of flowering, availability of pollinators, successful pollination, and time needed seed maturity. Although the probability is low, GT alfalfa genes may be found in non-GT alfalfa but cannot be considered a significant impact because, among other factors, contractual "best practices" have been found to produce non-GT alfalfa seed with >99.5 percent purity.

Weeds in Alfalfa

- Biology/ecology of alfalfa (perennial status) and production practices (mowing, less glyphosate used compared to other crops) in alfalfa farming suggest that glyphosate-resistant weeds would be slow to develop, if they develop at all, due to GT alfalfa.

Impacts of GT Alfalfa on Wildlife and Plants

- GT alfalfa is not toxic to animals, will not compete with plants any differently than non-GT alfalfa, and has no significant effect on threatened or endangered species (T&E) or their critical habitat.

Herbicide Use

- Due to the use of glyphosate on GT alfalfa, overall glyphosate use may increase in alfalfa production, but such an increase should be not be a significant impact on the environment for several reasons:
 - Glyphosate is currently used on conventional alfalfa to “take out” (remove) an alfalfa field.
 - Use of other, more toxic herbicides will decrease in alfalfa production with the increased adoption and planting of GT alfalfa.
 - Glyphosate is environmentally less adverse than other herbicides (a lower environmental impact quotient compared to other herbicides currently used in alfalfa production). Thus, the net effect on alfalfa production with the increased adoption and planting of GT alfalfa should be some increased use of the less toxic glyphosate with a decreased use of more toxic herbicides.
 - Animal threatened or endangered (T&E) species are not at risk, and terrestrial and semi-aquatic T&E plants may be at some risk of direct effects from exposure to glyphosate used in agriculture, if they are found near alfalfa fields. All plants are at some risk of direct effects from exposure to herbicides currently used in alfalfa production.

Socioeconomic Impacts

- *Businesses Lost and Gained*
 - Farmers adopting GT alfalfa may have decreased costs or improved markets as GT-sensitive farmers may have a reduction in demand.
 - Early GT alfalfa adopters may gain markets while conventional non-GT alfalfa farmers producing high quality alfalfa may lose markets, due to potentially higher costs and lower quality of conventional non-GT alfalfa when compared to GT alfalfa.
 - If there is GT-sensitivity in the market for organic alfalfa, organic farmers most affected by the unintended presence of GT alfalfa may lose some markets (decrease the quantity sold), while organic farmers less affected by the unintended presence of GT alfalfa may expand their markets (increase the quantity sold).
 - Although individual farmers may be affected, when examined in total, none of the potential business losses or

gains are expected to be so severe as to amount to a significant impact.

- *Market Structure*

- Overall, alfalfa production may shift to larger farms.
 - If purchasing land to provide a separation distance between GT and non-GT alfalfa is the only mechanism used to minimize the presence of GT alfalfa in GT-sensitive alfalfa fields, these increased land costs could benefit larger non-GT alfalfa farmers.
 - To the extent that organic farming is more suitable for small farms than conventional farming (less economies of scale related to greater dependency on labor), a reduction in the demand for organic products could favor larger farmers.
 - However, land needs for GT-sensitive alfalfa forage growers may be reduced as there are other mechanisms available to minimize the presence of GT alfalfa in GT-sensitive alfalfa fields.
- If adoption rates of GT alfalfa were high, alfalfa seed farmers may find an increased demand for GT alfalfa seeds and could shift production to this variety.

- *Distribution of Costs of Loss of Production and Avoidance*

- Organic producers could have either a loss of production or need to add additional measures to reduce the likelihood of unintended presence if 1) there is an amount of GT alfalfa in organic alfalfa that the organic market will reject, or 2) current alfalfa production practices are not already in place to protect against unintended presence of GT alfalfa in GT-sensitive alfalfa fields. There is no evidence that supports either of these assumptions.

- *Social Aspects of Organic Farming*

- The analyses found no GE-sensitivity in domestic sales of organic alfalfa; however, this does not mean that GE products are necessarily welcome by organic consumers or producers. It is difficult to empirically quantify GE-sensitivity in the domestic sales of organic alfalfa and by-products in the marketplace because: there are no governmental standards for GE content in organic products; organic standards are process-based, not product-based (organic processes do not require a GE-free product); and researchers cannot quantify real-world preferences as consumers do not have the means to accurately discern between GE and non-GE products.

Human Health and Safety

- GT alfalfa has no adverse effects on human health and worker safety.
- Overall risk of glyphosate use to human health and worker safety does not change with the adoption of GT alfalfa. The EPA has determined that the use in accordance with the labeling of currently registered pesticide products containing glyphosate will not pose unreasonable risks or adverse effects to humans or the environment, including its use on alfalfa.

Land Use and Physical Environment

- Overall land devoted to alfalfa cultivation will be impacted largely by the price of alfalfa hay and not by the availability of GT technology.
- GT alfalfa is not expected to have an adverse impact on soils, climate or air quality, or water and water use.

In summary, the impacts analyses in this DEIS have not found any significant impacts of GT alfalfa on the biological properties of alfalfa, weediness, threatened and endangered species, wildlife, other plants, other agricultural production systems and markets, trade, human health and safety, land use or the physical environment. Although glyphosate may likely increase in alfalfa agriculture due to the adoption of GT alfalfa, the number and use of other, more toxic herbicides will decrease, and there is no significant impact of glyphosate use on weediness of alfalfa, glyphosate-resistant weeds, human health and safety, land use or the physical environment.

The draft environmental impact statement will have a 60-day comment period. We will consider all public comments received during the comment period in preparation of the final environmental impact statement.

I. Purpose and Need

A. Introduction

"Protecting American agriculture" is the basic charge of the U.S. Department of Agriculture's (USDA) Animal and Plant Health Inspection Service (APHIS). APHIS provides leadership in ensuring the health and care of plants and animals. By ensuring plant and animal health, the agency improves agricultural productivity and competitiveness, and contributes to the national economy and the public health. USDA asserts that all methods of agricultural production (conventional, organic, and the use of genetically engineered varieties) can provide benefits to the environment, consumers, and farm income.

One of APHIS' many functions is to regulate the introduction of genetically engineered (GE) organisms, including crop and noncrop plants, vertebrate and invertebrate animals, and microorganisms that might pose a plant pest risk. Genetic engineering refers to the process in which genes or other genetic elements from one or more organisms are inserted into the genetic material of a second organism using molecular biology methods. Moving a new gene or genes in this way allows researchers to introduce useful new traits into an organism from individuals of the same species or from unrelated species.

GE organisms are subject to APHIS oversight if they have the potential to pose a plant pest risk as defined in the regulations at 7 Code of Federal Regulations (CFR) part 340. After appropriate analysis, APHIS may determine that a GE organism is unlikely to pose a plant pest risk and grant that GE organism nonregulated status. APHIS has been petitioned by Forage Genetics International (FGI) and the Monsanto Company to grant nonregulated status to two lines of GE alfalfa, J101 and J163, that are tolerant of applications of glyphosate, an herbicide. This draft environmental impact statement (DEIS) was prepared to comply with an order from the United States District Court for the Northern District of California to identify and analyze any environmental impacts associated with APHIS' determination on whether to grant nonregulated status to GE alfalfa lines J101 and J163.

B. Regulatory Authority

In 1986, the Federal Government's Office of Science and Technology Policy (OSTP) published a policy document known as the Coordinated Framework for the Regulation of Biotechnology (51 *Federal Register* (FR) 23302). This document specifies three Federal agencies that are responsible for regulating biotechnology in the United States: USDA's APHIS, the U.S. Department of Health and Human Services' Food and

Drug Administration (FDA), and the Environmental Protection Agency (EPA).

1. USDA

The APHIS Biotechnology Regulatory Service's (BRS) mission is to protect America's agriculture and environment using a dynamic and science-based regulatory framework that allows for the safe development and use of genetically engineered organisms. APHIS regulations at 7 CFR part 340, which were promulgated pursuant to authority granted by the Plant Protection Act, as amended (7 United States Code (U.S.C.) 7701–7772), regulate the introduction (importation, interstate movement, or release into the environment) of certain GE organisms and products. A GE organism is considered a regulated article if the donor organism, recipient organism, vector, or vector agent used in engineering the organism belongs to one of the taxa listed in the regulation (7 CFR § 340.2) and is also considered a plant pest. A GE organism is also regulated under part 340 when APHIS has reason to believe that the GE organism may be a plant pest or APHIS does not have sufficient information to determine if the GE organism is unlikely to pose a plant pest risk.

A person may petition the agency to evaluate submitted data and determine that a particular regulated article is unlikely to pose a plant pest risk, and, therefore, should no longer be regulated, under 7 CFR § 340.6 "Petition for Determination of Nonregulated Status." The petitioner is required to provide information (§ 340.6(c)(4)) related to plant pest risk that the agency uses to determine whether the regulated article is unlikely to present a greater plant pest risk than the unmodified organism. An organism is no longer subject to the regulatory requirements of 7 CFR part 340 when APHIS determines that it is unlikely to pose a plant pest risk.

2. FDA

FDA regulates under the authority of the Federal Food Drug and Cosmetic Act (FFDCA). FDA is responsible for ensuring the safety and proper labeling of all plant-derived foods and feeds, including those developed through genetic engineering such as glyphosate-tolerant alfalfa. All foods and feeds, whether imported or domestic and whether derived from plants modified by conventional breeding techniques or by genetic engineering techniques, must meet the same rigorous safety standards. Under the FFDCA, it is the responsibility of food and feed manufacturers to ensure that the products they market are safe and properly labeled. In addition, any food additives, including ones introduced into food or feed by way of plant breeding, must receive FDA approval before marketing. To help developers of foods and feeds derived from GE plants to comply with their obligations, FDA encourages them to participate in its voluntary consultation process. In that process, developers submit to FDA data and information that provide the basis for a conclusion that a GE food is as

safe as comparable non-GE food in the food supply. FDA believes that developers of bioengineered food that is intended to be commercially marketed have followed the recommendations in FDA's guidance documents for consulting with FDA.

The FDA policy statement concerning regulation of products derived from new plant varieties, including those genetically engineered, was published in the *Federal Register* on May 29, 1992 (57 FR 22984-23005). Under this policy, FDA uses what is termed a consultation process to ensure that human food and animal feed safety issues or other regulatory issues (e.g., labeling) are resolved prior to commercial distribution of bioengineered food. Products are regulated according to their intended use and some products are regulated by more than one agency.

3. EPA

Through a registration process that is independent of APHIS, EPA regulates the sale, distribution, and use of pesticides in order to protect health and the environment. This registration process includes the registration of pesticides that are produced by organisms developed using techniques of modern biotechnology. Under the Federal Insecticide, Fungicide and Rodenticide Act (FIFRA), the Biopesticides and Pollution Prevention Division of the Office of Pesticide Programs regulates the distribution, sale, use, and testing of pesticidal substances produced in plants and microbes, as well as the microbes themselves, if EPA considers them to be biocontrol agents or pesticidal in function. Under FIFRA, EPA also regulates the herbicides that are applied to GE herbicide-tolerant crops, such as glyphosate-tolerant (GT) alfalfa. Under FFDCA, EPA regulates pesticide residues. Additionally, under section 5 of the Toxic Substances Control Act (TSCA), EPA acquires information in order to identify and regulate potential hazards and exposures of all new chemicals intended for entry into commerce that are not specifically covered by other regulatory authorities, for example, substances other than food, drugs, cosmetics, and pesticides. TSCA's applicability to the regulation of products of biotechnology is based on the interpretation that microorganisms are chemical substances under TSCA.

Together, these agencies ensure that the products of modern biotechnology are safe to grow, safe to eat, and safe for the environment. USDA, EPA, and FDA enforce agency-specific regulations regarding products of biotechnology that are based on the specific nature of each GE organism.

C. Glyphosate-Tolerant Alfalfa

On April 16, 2004, APHIS received a petition from Monsanto Company of St. Louis, Missouri and Forage Genetics International of West Salem, Wisconsin (Monsanto and FGI), requesting a determination of nonregulated status under 7 CFR part 340 for two alfalfa (*Medicago sativa*

L.) lines designated as J101 and J163, which have been genetically engineered for tolerance to the herbicide glyphosate. The Monsanto and FGI petition stated that the two GT alfalfa lines should not be regulated by APHIS because they do not present a plant pest risk.

Alfalfa plants, like most plants, produce an enzyme called 5-enolpyruvylshikimate-3-phosphate synthase (EPSPS). EPSPS is necessary for the production of certain amino acids essential for plant growth. Alfalfa plants were genetically engineered by inserting a bacterial gene (from *Agrobacterium* sp. strain CP4), responsible for the production of a different 5-enolpyruvylshikimate-3-phosphate synthase (CP4-EPSPS), into the alfalfa genome. This gene, along with its regulatory sequences, was introduced into these alfalfa plants via the well-characterized *Agrobacterium*-mediated transformation method. Two different, genetically independent alfalfa lines, J101 and J163, were produced using this transformation method.

Glyphosate is an herbicide, a chemical that kills plants, and it kills plants by inhibiting the activity of EPSPS. Glyphosate is a "non-selective" herbicide, which means that almost all plant species are killed when sprayed with enough glyphosate because almost all plants need normal EPSPS activity for growth. Alfalfa plants genetically engineered to produce CP4-EPSPS are glyphosate-tolerant because glyphosate does not inhibit the activity of CP4-EPSPS. If alfalfa plants producing CP4-EPSPS are growing in a field with weeds, applying glyphosate to the field will kill the weeds but not the alfalfa plants.

Monsanto and FGI completed FDA's voluntary consultation process for both lines of GT alfalfa. The FDA letter to Monsanto and FGI, and analysis by FDA, in response to their submission regarding GT alfalfa lines J101 and J163 can be found at <http://www.cfsan.fda.gov/~lrd/biocon.html> and appendix P.

a. History

1. National Environmental Policy Act Processes

APHIS evaluated the plant pest risks posed by the nonregulated use of lines J101 and J163 and prepared an environmental assessment (EA) to identify and evaluate any environmental impacts resulting from the approval of the petition. In a notice published in the *Federal Register* on June 27, 2005 (70 FR 36917-36919, Docket No. 04-085-3), APHIS advised the public of its determination, effective June 14, 2005, that the Monsanto and FGI GT alfalfa lines J101 and J163 were no longer considered regulated articles under 7 CFR part 340.

Approximately 9 months later, a group of organic alfalfa growers and several other associations filed a lawsuit in the U.S. District Court for the

Northern District of California that challenged APHIS' decision to grant nonregulated status to J101 and J163.¹ On February 13, 2007, the Court ruled that APHIS' EA failed to adequately consider certain environmental and economic impacts as required by the National Environmental Policy Act (NEPA), and the Court vacated APHIS' decision to grant nonregulated status to J101 and J163. The Court also ordered APHIS to prepare a NEPA-compliant environmental impact statement (EIS) before deciding whether to grant nonregulated status to J101 and J163. On March 23, 2007, APHIS published a notice in the *Federal Register* (72 FR 13735-13736 APHIS Docket No. 04-085-1) announcing the Court's decision that Monsanto and FGI GT alfalfa lines J101 and J163 were once again regulated articles under 7 CFR part 340. GT alfalfa seed sales and planting were halted.

Once the GT alfalfa lines were deregulated in June 2005, those GT alfalfa lines' seeds were sold and plantings were started. In the two growing seasons (2005 and 2006) that GT alfalfa was on the market, ~200,000 acres were planted in 1,552 counties and 48 states with the exception of Alaska and Hawaii. These GT alfalfa fields are still permitted to be harvested, and have court ordered stewardship practices to minimize the potential of GT alfalfa being present in harvests of non-GT alfalfa harvests (Hubbard, 2008).

b. Scoping

The granting of nonregulated status to GT alfalfa lines raises a number of issues that may be addressed in this DEIS. These issues were identified by the agency through a scoping process. Public scoping is required under NEPA, as amended, Council on Environmental Quality (CEQ) regulations for implementing NEPA, the USDA regulations implementing NEPA, and APHIS' National Environmental Policy Act of 1969 (NEPA) Implementing Procedures. Scoping for this DEIS began on January 7, 2008, when APHIS gave notice in the *Federal Register* (73 FR 1198-1200) of its intent to prepare a DEIS. The notice listed several questions to be discussed in the EIS—

- (1) What are the particular management practices for organic alfalfa, conventional alfalfa, and glyphosate-tolerant alfalfa? What are the procedures and associated costs of establishing, growing, harvesting, and marketing (includes selling prices and premiums for various quality standards) for each of the three types of alfalfa? What crop rotation regimes are used with each type of alfalfa?
- (2) What are the production levels of organic and conventional alfalfa seed and hay by region, State, and county? Which regions of the

¹ The lawsuit raised claims under the National Environmental Policy Act (NEPA), the Endangered Species Act (ESA), and the Plant Protection Act (PPA).

country areas may be affected more than others with the deregulation of glyphosate-tolerant alfalfa? What is the acreage of cultivated, volunteer, or feral alfalfa? What are the potential impacts on adjacent, nonagricultural lands such as natural areas, forested lands, or along transportation routes that may occur with the use of GT alfalfa?

- (3) What is the expected effect of GT alfalfa release on animal production systems?
- (4) What are the potential impacts of GT alfalfa release on food and feed? How does glyphosate tolerance affect food or feed value or nutritional quality? Should the low level presence of GT alfalfa occur in situations where it is unwanted, unintended, or unexpected, what impact would this have on the ability of producers to market affected organic or conventional alfalfa or livestock fed this material? What are the negative impacts, if any, on food or feed value or quality from the use of glyphosate?
- (5) What differences are there in weediness traits of conventional alfalfa versus GT alfalfa under managed crop production systems as well as in unmanaged ecosystems?
- (6) What is the occurrence of common and serious weeds found in organic alfalfa systems, in conventional alfalfa systems, and in GT alfalfa systems? What are the current impacts of weeds, herbicide-tolerant weeds, weed management practices, and unmet weed management needs for organic and conventional alfalfa cultivation? How may the weed impacts change with the use of GT alfalfa?
- (7) What are the particular management practices for controlling weeds in organic alfalfa systems, in conventional alfalfa systems, and in GT alfalfa systems? What are the potential changes in crop rotation practices and weed management practices for control of volunteer alfalfa or herbicide-tolerant weeds in rotational crops that may occur with the use of GT alfalfa? What are the potential effects on alfalfa stand termination and renovation practices that may occur with the use of GT alfalfa? What is the potential weediness of GT alfalfa?
- (8) What is the potential cumulative impact of glyphosate-resistant weeds, especially with the increase in acreage of GT crops? Are there glyphosate-resistant weeds and what is their prevalence in crops and in non-crop ecosystems? Will the release of GT alfalfa cause an increase in glyphosate-resistant weeds in alfalfa and in other crops? Which weeds are the most likely to gain glyphosate resistance with the use of GT alfalfa? What are the alternatives for management of GT or other herbicide-tolerant weeds in GT alfalfa stands or in subsequent crops? What are the potential changes that may occur in GT alfalfa as to susceptibility or tolerance to other herbicides?

- (9) What are current or prospective herbicide-tolerant weed mitigation options, including those addressed by the EPA-approved label for glyphosate herbicides?
- (10) What is the potential for gene flow in all combinations between seed fields, hay fields, and feral plants? To what extent will deregulation of GT alfalfa impact hybridization between cultivated and feral alfalfa, alfalfa's introgression or establishment outside of cultivated lands, and alfalfa's persistence in situations where it is unwanted, unintended, or unexpected? What are the risks associated with feral GT alfalfa plants? How will the removal of GT alfalfa in situations where it is unwanted, unintended, or unexpected result in adverse impacts? In such situations, how will GT alfalfa be controlled or managed differently from other unwanted, unintended, or unexpected alfalfa? To what extent can organic or conventional alfalfa farmers prevent their crops from being commingled with unwanted, unintended, or unexpected GT alfalfa?
- (11) What are the potential economic and social impacts of GT alfalfa release on organic and conventional alfalfa farmers? What are the potential impacts of the presence of GT alfalfa caused by pollen movement or seed admixtures? What are the economic issues associated with using alfalfa seed or hay commingled with GT alfalfa? What are the particular economics of growing seed or hay of organic alfalfa, conventional alfalfa, or GT alfalfa? What are the potential changes in the economics of growing and marketing organic and conventional alfalfa that may occur with the use of GT-tolerant alfalfa? What are the potential changes in production levels of other crops that may occur with the use of GT alfalfa (i.e., will the release of GT alfalfa result in more or fewer acres of corn, wheat, other forage crops, etc.)? What are the potential changes in growing practices, management practices, and crop rotational practices in the production of alfalfa hay or seed for planting or sprouting purposes that may occur with the use of GT alfalfa? What are the potential changes in the choice of seeds available for organic and conventional alfalfa farmers that may occur with the use of GT alfalfa?
- (12) What are the potential impacts of the deregulation of GT alfalfa on U.S. trade? If the presence of GT alfalfa should occur in organic or conventional alfalfa where it is unwanted, unintended, or unexpected, what are the expected impacts on trade with countries that normally import alfalfa seed or hay? What are the expected impacts on trade with countries that do not normally import alfalfa? Is there an expected impact on trade in other commodities?
- (13) What is the potential cumulative impact of increased glyphosate usage with the release of GT crops? Have changes in glyphosate usage impacted soil quality, water quality, air quality, weed populations, crop rotations, soil microorganisms, diseases, insects, soil fertility, food or feed quality, crop acreages, and crop yields?

Does the level of glyphosate tolerance within GT alfalfa plants have a major impact on the amount of glyphosate applied on the GT alfalfa crop on a routine basis?

- (14) What are the potential impacts of the release of GT alfalfa on threatened or endangered species and designated critical habitat? What are the potential effects of GT alfalfa use on listed threatened or endangered species, species proposed for listing, designated critical habitat, or habitat proposed for designation? What are the potential effects of glyphosate use on listed threatened or endangered species, species proposed for listing, designated critical habitat, or habitat proposed for designation; including glyphosate used on GT alfalfa?
- (15) What are the potential health and safety risks to field workers or other workers that would come into contact with GT alfalfa?
- (16) Can any of the potential negative environmental impacts resulting from the deregulation of GT alfalfa be reasonably mitigated, and what is the likelihood that mitigation measures will be successfully implemented? The EIS will consider the stewardship measures outlined in the addendum to section VIII of the petition, as well as any other mitigation measures APHIS considers applicable and viable. Such measures, some of which may be outside the jurisdiction of APHIS, are designed to reduce inadvertent gene flow of GT alfalfa to negligible levels, as well as to monitor and minimize the potential development of GT weeds.
- (17) What are the impacts of the mitigation measures on coexistence with organic and conventional alfalfa production and export markets?
- (18) Are there any other potential direct, indirect or cumulative impacts from the release of GT alfalfa other than those mentioned above?

The notice solicited public involvement in the form of written comments regarding the above issues and alternatives for regulatory action. Written comments were accepted from the public during a comment period which lasted until February 6, 2008 (<http://www.regulations.gov/fdmspublic/component/main?main=DocketDetail&d=APHIS-2007-0044> and appendix B).

c. Scoping Analysis and Documentation

All comments and proposed alternatives received were evaluated on the basis of whether they addressed the issues in question, whether they were based on valid science, and whether they were reasonable and practicable. A summary of the public comments are provided in appendix B. The results of the scoping process assisted APHIS in the formulation of the alternatives that are analyzed in this DEIS. Relevant issues raised through the scoping process were incorporated into the formulation of the

regulatory alternatives as described in chapter 2 and issues discussed in chapters 3 and 4.

Under the authority of 7 CFR part 340, APHIS has the responsibility for overseeing the safe development and use of GE organisms under the provisions of the Plant Protection Act. APHIS must respond to petitioners that request a determination of the regulated status of GE organisms, including GE crop plants such as GT alfalfa events J101 and J163. If a petition for nonregulated status is submitted, APHIS must make a determination whether the GE organism is unlikely to pose a plant pest risk.

As a Federal agency subject to compliance with the National Environmental Policy Act (NEPA) (42 U.S.C. 4321 et seq.), APHIS has prepared this DEIS to consider the potential environmental effects of this proposed action (granting nonregulated status) and the reasonable alternatives to that action consistent with NEPA regulations (40 CFR parts 1500-1508, 7 CFR 1b, and 7 CFR part 372). This DEIS has been prepared to comply with an order of the U.S. District Court for the Northern District of California to evaluate the effects on the quality of the human environment that may result from the deregulation of GT alfalfa lines J101 and J163.

d. How the Draft Environmental Impact Statement was Developed

On January 7, 2008, APHIS published in the *Federal Register* a Notice of Intent (NOI) (73 FR 1198-1200) to prepare an EIS, in compliance with NEPA and APHIS' own NEPA implementation rules. The purpose of the EIS is to identify and analyze any environmental impacts that could result from the granting of nonregulated status to two lines of genetically engineered, GT alfalfa, designated J101 and J163. As described in chapter 1, the NOI posed several questions in broad categories related to issues that could be of concern. The 30-day comment period closed on February 6, 2008. Approximately 240 public comments were received and reviewed by APHIS. These and all other comments were analyzed, and APHIS identified any new issues not originally provided in the NOI.

APHIS used all the comments that it collected from the *Federal Register* notice to ensure that the agency was addressing all pertinent issues, and that the EIS examined environmental impacts that could result from deciding to grant or not to grant nonregulated status to GT alfalfa lines J101 and J163. The results of the scoping process and NOI are summarized in appendix B.

2. Requirements for Further Environmental Analysis

APHIS will issue a final EIS that addresses public comments received on this DEIS, in accordance with NEPA. Supplements to the final EIS may be necessary as new information is brought to APHIS' attention, changes occur in the program or its administration, or coverage of the document is expanded. Two classes of supplements could be issued:

- Insignificant Supplements—Supplements that cause no substantive change in emphasis or classes of activities and do not have significant environmental impacts (40 CFR § 1508.27).
- Significant Supplements—Supplements that substantively change program emphasis or that have potentially “significant” impacts to the environment (40 CFR § 1508.27).

Insignificant supplements will be made by the APHIS Administrator or his or her delegated representative with appropriate public notification. Significant supplements will be subjected to NEPA analysis and put in force with the appropriate NEPA documentation and determination as required by CEQ and APHIS–NEPA implementing regulations.

II. Alternatives

A. Introduction

The U.S. Department of Agriculture (USDA) Animal and Plant Health Inspection Service (APHIS) is responsible for regulating the introduction (importation, interstate movement, and environmental release) of genetically engineered (GE) organisms that are known to, or could, pose a plant pest risk. GE organisms are considered to have the potential to pose a plant pest risk if the donor organism, recipient organism, vector, or vector agent used in their creation is a member of a genus (listed in the regulations at 7 CFR part 340) known to contain plant pests.

A person may petition the agency to evaluate submitted data and determine that a particular regulated article is unlikely to pose a plant pest risk, and, therefore, should no longer be regulated, under 7 CFR § 340.6 “Petition for Determination of Nonregulated Status.” The petitioner is required to provide information (§ 340.6(c)(4)) related to plant pest risk that the agency uses to determine whether the regulated article is unlikely to present a greater plant pest risk than the unmodified organism. If, based on this information, the agency determines that the article is unlikely to pose a plant pest risk, the agency may approve the petition, the regulated article may be granted deregulated status, and APHIS is divested of regulatory authority over this GE organism.

A. Description of Alternatives

This draft EIS analyzes the potential environmental consequences of a proposal to grant nonregulated status to glyphosate-tolerant (GT) alfalfa lines J101 and J163. USDA asserts that all production systems, conventional, organic, and the use of genetically-engineered varieties, provide benefits to agriculture and the environment, thus the alternatives have been developed in conjunction with this philosophy.

In order for a GE organism to be granted nonregulated status, it must be unlikely to pose a plant pest risk. The analysis provided in the plant pest risk assessment (USDA-APHIS, 2009) demonstrates that there was sufficient data to determine that both GT alfalfa lines J101 and J163 are unlikely to pose a plant pest risk. Once APHIS determines that the GT alfalfa lines do not pose a plant pest risk, APHIS would have no regulatory authority over GT alfalfa events J101 and J163 and these GT alfalfa lines are eligible for nonregulated status.

The regulations at 7 CFR § 340.6(d)(3)(i) state that APHIS may “approve the petition in whole or in part.” Approval ‘in part’ can be given if there is

a plant pest risk associated with some but not all lines requested in a petition.

APHIS has removed from consideration the concept of approving only one of the genetically-engineered GT alfalfa lines (either J101 or J163) and not both lines. APHIS conducted a risk assessment of the plant pest risks posed by GT alfalfa lines J101 and J163 (USDA-APHIS, 2009). The risk assessment of GT alfalfa J101 and J163 indicates that neither J101 and J163 pose a plant pest risk: 1) the two lines show no evidence of increased weediness compared to the non-transgenic control; 2) neither line exhibits increased insect or disease susceptibility; 3) the genetic sequences from plant pests inserted into the alfalfa lines do not pose a plant pest risk; and 4) neither line exhibits increased plant pest risk characteristics. There are also no significant biological differences between the two lines in terms of transgene protein expression and composition (chapter 3). Additionally, none of the comments received during the public comment period of the original EA in 2005 (USDA, 2005) and during the public comment period of the NOI cited concerns regarding a difference in or occurrence of any plant pest risks in GT alfalfa lines J101 and J163. Since there are no biological differences between GT alfalfa lines J101 and J163 (and the public comments did not call attention to any perceived differences in GT alfalfa lines J101 and J163), and since there is no plant pest risk associated with either alfalfa line, there is no environmental or public health advantage in granting nonregulated status to one line over the other GT alfalfa line. Therefore, APHIS will only issue a decision in conjunction with both GT alfalfa lines and will not consider granting nonregulated status to only one of the GT alfalfa lines.

Because APHIS has found that both GT alfalfa lines J101 and J163 are unlikely to pose a plant pest risk, the preferred alternative considered in this DEIS is to grant nonregulated status “in whole.” Under another type of granting nonregulated status there could be approval “in part,” where the petition may be approved with geographic restrictions if there is a geographic variation in plant pest risk. There are no geographic differences in plant pest risks for these GE alfalfa lines (USDA-APHIS, 2009). Thus, there are two alternatives that will be considered in this draft EIS: (1) no action and (2) to grant nonregulated status to GT alfalfa events J101 and J163, “in whole.”

1. No Action

Under the "no action" alternative, APHIS would not change the regulated status of glyphosate-tolerant (GT) alfalfa lines J101 and J163 under the regulations in 7 CFR part 340. As stated in the Purpose and Need, chapter 1, GT alfalfa lines J101 and J163 were granted nonregulated status by APHIS in 2005. Approximately 9 months later, a group of organic alfalfa growers and several other associations filed a lawsuit in the U.S. District Court for the Northern District of California that challenged

APHIS' decision to grant nonregulated status to J101 and J163. On February 13, 2007 the Court ruled that APHIS' EA failed to adequately consider certain environmental impacts as required by the National Environmental Policy Act of 1969 (NEPA), and the Court vacated APHIS' decision to grant nonregulated status to J101 and J163. In March of 2007 USDA published notice in the Federal Register that GT alfalfa was once again a regulated article and GT alfalfa seed sales and plantings were halted.

In the two growing seasons that GT alfalfa was on the market after being deregulated, ~200,000 total acres were planted in 1,552 counties and 48 States, with the exception of Alaska and Hawaii, during the 2005 and 2006 growing seasons. These GT alfalfa fields are still permitted to be harvested, and has court ordered stewardship practices to minimize potential of GT alfalfa being present in harvests of non-GT alfalfa harvests (Hubbard, 2008).

Under the no action alternative, the approximately 200,000 acres of alfalfa fields currently planted with GT alfalfa would still be permitted to be harvested. No new commercial plantings of GT alfalfa would be allowed because GT alfalfa lines J101 and J163 would continue to be considered regulated articles. APHIS would require permits for new introductions of GT alfalfa events J101 and J163, and these introductions would only be for non-commercial, research and development purposes.

This alternative is not the preferred alternative because APHIS has determined through a plant pest risk assessment (USDA-APHIS, 2009) that the GT alfalfa lines under consideration are not plant pests and are unlikely to pose plant pest risks. Choosing this alternative would hinder the purpose and need of APHIS to allow for the safe development and use of GE organisms given that GT alfalfa lines J101 and J163 are unlikely to pose plant pest risks.

2. Determination that J101 and J163 Alfalfa Plants are No Longer Regulated Articles, In Whole (Preferred Alternative)

Under the preferred alternative, GT alfalfa lines J101 and J163 would no longer be regulated articles under the regulations at 7 CFR part 340. Permits issued by APHIS would no longer be required for introductions of GT alfalfa derived from these events. Additional acreage planted to GT alfalfa, in addition to the ~200,000 acres of GT alfalfa currently planted, would be allowed.

Once APHIS has determined that GT alfalfa lines J101 and J163 are unlikely to pose a plant pest risk, APHIS would not have regulatory authority over these GE organisms. By granting nonregulated status to GT alfalfa lines J101 and J163 since they do not pose a plant pest risk, the purpose and need to allow the safe development and use of GE organisms is met.

With respect to the issues and associated alternatives, APHIS has made a preliminary determination that action should be taken, and that action will be to grant nonregulated status to GT alfalfa lines J101 and J163, in whole (Alternative 2). The introduction of these GT alfalfa lines has no significant impact on the environment. These GT alfalfa plants, lines J101 and J163, are not plant pests and are unlikely to pose plant pest risks. GT alfalfa lines J101 and J163 do not meet the definition of a regulated article under 7 CFR part 340.

A. Alternatives Rejected from Further Consideration

APHIS assembled a comprehensive list of alternatives that might be implemented in the decision process for lines J101 and J163 of GT alfalfa. The agency individually evaluated each alternative on the basis of legality, environmental safety, efficacy, and practicality to identify which alternatives would be further considered during the decision process. Based on this evaluation, APHIS rejected several alternatives. In the interest of transparency, these alternatives are discussed briefly below along with the specific reasons for rejecting each.

1. Prohibit Glyphosate- Tolerant Alfalfa

In response to public comments submitted during scoping that stated a preference that no GE organisms enter the marketplace, APHIS considered prohibiting the release of any GT alfalfa, including denying any permits associated with the continued environmental releases or field testing of GT alfalfa. APHIS determined that this alternative is not appropriate in that GT alfalfa events J101 and J163 have been determined in APHIS' Plant Pest Risk Assessment not to be plant pests (USDA-APHIS, 2009). APHIS has no jurisdiction to regulate plants as plant pests once APHIS has determined that those plants are not plant pests.

A risk-management process based on sound science must consider a growing body of scientific evidence documenting the safe use of GE organisms in U.S. agriculture, and in the rest of the world, to determine whether their use poses any unacceptable risks. Because Congress has mandated a science-based approach in APHIS regulations and because there is no basis in science for banning the release of GT alfalfa, a blanket prohibition of the release of GT alfalfa would contravene Congressional intent and must be rejected.

2. Impose Isolation Distances

In response to public comments submitted during scoping that described concerns about the gene movement between GE and non-GE plants, APHIS considered requiring isolation distances separating GT alfalfa from non-GT alfalfa fields. However, because GT alfalfa is unlikely to pose a plant pest risk (USDA-APHIS, 2009), APHIS will have no regulatory authority over GT alfalfa and will be unable to require regulatory

restrictions or management practices for these GE alfalfa varieties once it is granted nonregulated status.

**3. Impose
Geographic
Restrictions**

In response to public comments submitted during scoping that described concerns about the gene movement between GE and non-GE plants, APHIS considered geographic restrictions based on regional growing practices of alfalfa or regional changes in pesticide use that may significantly affect the environment due to use of J101 or J163. In the regional analysis of production practices of alfalfa, no significant differences were detected at a regional level (see chapter 3), so this alternative was dismissed.

APHIS considered restricting the production of GT alfalfa based on production of non-GT alfalfa in organic production systems or production systems for GE-sensitive markets. State-level and county-level restrictions of GT alfalfa, as well as the establishment of GE-free alfalfa production zones, were rejected because GT alfalfa is unlikely to pose a plant pest risk (USDA-APHIS, 2009). Therefore, APHIS will have no regulatory authority over GT alfalfa and will be unable to impose regulatory restrictions on these GE alfalfa varieties.

**4. Impose
Testing
Requirement**

During the comment periods for other petitions for granting nonregulated status, and during the scoping period for this DEIS, some commenters have requested that USDA require and provide testing for GE products in non-GE production systems. However, there are no nationally established regulations involving testing or limits of GE material in non-GE systems. As a member of the Biotechnology Industry Organization (BIO), Monsanto and FGI are pledging to work with the framework of the new BIO Quality Management Program (www.bio.org). Additionally, because GT alfalfa is unlikely to pose a plant pest risk (USDA-APHIS, 2009), APHIS will have no regulatory authority over GT alfalfa, and will be unable to impose regulatory restrictions on these GE alfalfa varieties.

III. Affected Environment

A. Overview of Alfalfa

Alfalfa (*Medicago sativa* L.) is among the most important forage crops in the United States, with more than 20 million acres in cultivation. It is recognized as the oldest plant grown solely for forage. Conventional alfalfa (alfalfa that is not a GE variety and not grown using organic practices) has been used by farmers as livestock feed for decades because of its high protein and low fiber content. Alfalfa ranks fourth on the list of most widely grown crops by acreage, behind corn, soybeans, and wheat, and is ranked third among agricultural crops in terms of value. Because it is widespread and is typically grown as a perennial crop, alfalfa also provides important habitat for wildlife (Hubbard, 2008).

Dairy farmers would be the most likely users of glyphosate-tolerant (GT) alfalfa because they often depend on pure alfalfa stands that are free of weeds and grasses, whereas, beef cattle producers and horse owners typically feed their animals a mix of alfalfa-grass hay (Putnam, 2005). About 40 percent of U.S. alfalfa acreage is planted as pure stands, and about 25 percent is planted with grasses or another companion crop (Rogan and Fitzpatrick, 2004).

Alfalfa plants are also used for a variety of non-agricultural purposes. These uses include rehabilitation of overgrazed rangelands, erosion-control projects in interior forests, treatment of compacted soils, re-vegetation of areas damaged by wildfire, and erosion reduction in mined soils.

1. Uses of Alfalfa

The following discussion is in part taken from the technical report, *Effects of Glyphosate-Resistant Weeds in Agricultural Systems* (appendix G).

a. Seed

Humans consume alfalfa in the form of sprouts, dietary supplements, and herbal teas. The seed grown for sprouts is subject to more stringent restrictions for chemical applications during growing because the chemicals must be evaluated as food residues. Epidemiological (disease related) investigations have suggested that alfalfa seeds are the likely source in most, if not all, sprout-associated illness outbreaks. For these reasons, sprout seed and hay seed used for forage are usually grown separately (FDA, 1999).

In their Biotechnology Consultation, the Food and Drug Administration (FDA) concluded that the GT alfalfa events J101 and J163, and the feeds and foods derived from them, are not materially different in safety,

composition, or any other relevant parameter from alfalfa now grown, marketed, and consumed (appendix P). Thus, GT alfalfa is permitted for human consumption. However, Monsanto does not allow GT alfalfa to be planted for sprouts (Hubbard, 2008), a restriction that is enforced through signed agreements between Monsanto/Forage Genetics International (FGI) and purchasers of GT alfalfa.

b. Forage

Alfalfa is considered the “Queen of Forages” because of its high nutritional content for cattle and horses (Putnam et al., 2001). As alfalfa grows, yield increases until alfalfa yield peaks at full bloom. Nutritional content, however, is highest in young vegetative alfalfa plants and decreases as plants approach full flower. The highest quality alfalfa hay (bud stage) is generally used for dairy cows. Hay that is lower in protein and higher in fiber is fed to beef cattle, horses, heifers (too young to milk), and non-lactating dairy cows (Ball et al., 2001). Alfalfa for livestock feed is stored in a variety of forms such as hay (dry baled at 18- to 20-percent moisture); haylage (round bale silage, baled at 50- to 60-percent moisture and wrapped in plastic); and silage (chopped and blown into a silo or a truck).

c. Grazing

Grazing is sometimes used as an alternative to harvesting alfalfa. Grazing allows for high nutritional gains per animal, but the risks include animal losses due to gastro-intestinal bloating and difficulties in alfalfa stand maintenance if continuous grazing is present. Farmers may choose grazing for dormant-season alfalfa stubble, a substitute for early or late season cutting, and rotational grazing during the growing season (Orloff et al., 1997).

d. Other

Alfalfa and clover are common nectar sources for honey bee hives. Although alfalfa is not specifically grown for bees, both managed and wild bee hives are often associated with alfalfa fields (Hammon et al., 2007).

2. Biology of Conventional Alfalfa

a. Area of Adaptation

Alfalfa is recognized as a widely adapted crop, growing in all continental States, as well as Alaska and Hawaii. Alfalfa grows best in fertile, well-drained soils; however, because of its adaptability, it also survives outside of cultivation. Feral alfalfa populations, although sparse, occur throughout the United States (http://npdc.usda.gov/pdf/0105_npdc_brochure.pdf).

Little evidence exists to suggest that alfalfa is considered a weed (see appendices G and H), other than as a volunteer in agricultural settings. In correspondence with 13 weed control experts in Arizona, California, Idaho, Oregon, Pennsylvania, South Dakota, Washington, and Wisconsin, Monsanto found that none considered alfalfa a weed (Rogan and Fitzpatrick, 2004). In South Dakota and Wisconsin, it is encouraged to grow along roadsides.

b. Growth and Reproduction

Alfalfa is a deep-rooted and short-lived perennial. During establishment, alfalfa initially grows from seed, but after each harvest or winter, it re-grows from buds arising from the perennial root structure (the crown). Conventional alfalfa forage is grown in pure and mixed-species forage systems, or to a lesser extent, grazed in pasture or rangeland. The vegetative growth interval (i.e., harvest schedule) during most of the year is 22 to 40 days, and the crop is typically harvested for forage three to eight times per year, depending on location and seasonal climate. Fields grown for hay production are typically maintained for 3 to 6 years or longer in some areas. Most alfalfa in the United States is managed to limit growth to the juvenile (vegetative) state so that forage production (yield) and nutritional quality of the hay are optimized. Hay with open flowers or seed (late maturity) is of poor quality for feed and has low market value. In seed fields, flowering and seed production are promoted. In most fields, flower buds begin to form on stems approximately 4 to 6 weeks after field mowing during long-day photoperiods and warm weather. Flowering is not triggered under short days or cool weather (i.e., late summer through mid spring). Once flowering ensues, alfalfa flowers indeterminately, and its duration depends on moisture, temperature, and other factors (Rogan and Fitzpatrick, 2004).

Alfalfa is predominantly cross-pollinated and the flowers depend entirely on bees for cross-pollination. Wind cross-pollination in alfalfa does not occur (Viands et al., 1988). Alfalfa requires bees to physically “trip” flowers to release pollen for egg fertilization and seed production. In the United States, alfalfa seed production fields are pollinated primarily with leafcutter bees (*Megachile rotundata* F.) in the Pacific Northwest and honey bees (*Apis mellifera*) in California. Some growers in niche areas of southern Washington use alkali bees (*Nomia melanderi* C.), and certain seed producers use a blend of cultured species for pollination. Native bees, including *Bombus* spp., *Osmia* spp., *Agapostomen* spp., and *Megachile* spp., can be found visiting alfalfa in varying numbers. Other insect pollinators have not been shown to be effective for alfalfa (Rogan and Fitzpatrick, 2004).

c. Related Species

Alfalfa, of the genus *Medicago*, is in the tribe Trifolieae, which includes *Trifolium* (true clovers), *Melilotus* (sweetclover), and *Trigonella* (fenugreek). *Medicago* species do not hybridize (interbreed to form hybrid offspring) with these (or other) genera. The *M. sativa* complex has been successfully hybridized with 12 other perennial *Medicago* species (McCoy and Bingham, 1988). However, many of these interspecific hybrids have been successful only by using embryo culture of the hybrid in the greenhouse or laboratory (McCoy and Smith, 1986), making them highly unlikely to occur in nature. No perennial *Medicago* species are present naturally in the Americas, Australia, New Zealand, or South Africa, as it is native to the Middle East and Central Asia (Xu et al., 2004).

d. Susceptibility to Glyphosate and Other Herbicides

According to Crop Data Management System's (CDMS) Agricultural Product Label Service database, the herbicides 2,4-D, clopyralid, dicamba, glufosinate, glyphosate, and rimsulfuron-methyl were labeled for control of alfalfa. Independent research has demonstrated that dicamba, 2,4-D, tank mixtures of dicamba and 2,4-D, and clopyralid were often more effective than glyphosate for terminating alfalfa stands (Endres, 1999; Mayerle, 2002; Manitoba Agriculture and Food, 2002). Additional data demonstrated that early postemergence applications of herbicides (applied during the stage between the emergence of a seedling, and the maturity of the plant) used to control weeds in corn (Harness XTRA (acetochlor + atrazine), Degree (acetochlor), and Degree XTRA (acetochlor + atrazine) applied in tank mixtures with broadleaf herbicides Banvel (dicamba), 2,4-D, Marksman (atrazine + dicamba) and Hornet (clopyralid + flumetsulam) effectively controlled GT alfalfa in a GT corn crop. As expected, GT alfalfa events J101 and J163 were susceptible to herbicides typically used to control alfalfa² (Rogan and Fitzpatrick, 2004).

e. Susceptibility to Insect Damage and Disease

The major alfalfa diseases of economic importance in the United States are those pathogens that impact the foliar, crown, root, vascular, and seedling health of alfalfa plants. Alfalfa diseases are primarily caused by fungi; however, nematodes, bacteria, viruses, and other microbes also cause economic losses in alfalfa production (Leath et al., 1988). Diseases that occurred in the GT alfalfa test locations included, but were not limited to, seedling damping-off (caused by fungi such as *Pythium*, *Phytophthora*, *Aphanomyces*); foliar diseases (caused by fungi such as *Leptosphaerulina*, *Colletotrichum*, *Peronospora*, *Phoma*, *Stemphylium*,

² No unintended impacts or effects on other pest plant characteristics assessed by the manufacturers were found.

Cercospora, and stem nematodes like *Ditylenchus*); and root rots, vascular wilts and crown diseases (caused by fungi such as *Phytophthora*, *Verticillium*, *Fusarium*, *Phoma*, and bacterial wilt caused by *Clavibacter*) (Rogan and Fitzpatrick, 2004).

Insect pest species that are economically important in alfalfa vary widely among regions in the United States. The broad geographic distribution of the GT alfalfa test sites in the United States, and even broader exposure since deregulation in 2005, has exposed GT alfalfa to a wide range of naturally occurring insect pests. Insects that have an economic effect on the growing of GT and non-GT alfalfa included, but were not limited to potato leafhoppers (*Empoasca fabae*), aphids [pea (*Acyrtosiphon pisum*), blue (*A. kondoi*) and spotted alfalfa aphids (*Therioaphis maculata*)], alfalfa weevil (*Hypera postica*), lygus bugs (*Lygus species*), other plant bug species (family *Miridae*) and alfalfa caterpillars (various Lepidopteran species) (Rogan and Fitzpatrick, 2004).

f. Insertion of DNA Sequences

Monsanto and FGI has incorporated the gene sequence from a native soil microorganism, *Agrobacterium*, into the alfalfa genome in order to make alfalfa tolerant to glyphosate, the active ingredient in Roundup®, an herbicide Monsanto produces. As discussed in technical report, *Glyphosate-Tolerant Alfalfa Presence in Human Food and Animal Feed*, appendix Q), the expressed gene product in glyphosate-tolerant (GT) alfalfa is a protein, 5-enolpyruvylshikimate-3-phosphate synthase (EPSPS), derived from the CP4 strain of *Agrobacterium*, thus called CP4 EPSPS. The protein is a single polypeptide that is 455 amino acids long and structurally and functionally similar to the native plant EPSPS enzymes. The herbicide glyphosate inhibits an essential step in aromatic amine synthesis in plants by blocking the action of the natural EPSPS enzymes. However, the CP4 EPSPS protein is not inhibited by the herbicide glyphosate; thus any plant with the protein is resistant to glyphosate application. In other words, it is the insertion of this gene sequence and the production of the CP4 EPSPS protein that makes GE alfalfa events J101 and J163 tolerant to glyphosate and glyphosate herbicide formulations.

3. Feral Alfalfa

Since its introduction to the United States, alfalfa has occasionally become feral, or naturalized, by escaping agricultural fields and multiplying by natural regeneration. Settings where feral alfalfa can be found include air fields, canals, cemeteries, ditch banks, fence rows, highways, irrigation ditches, pipelines, railroads, rangeland, rights-of-way, roadsides, wasteland (Rogan and Fitzpatrick, 2004). Alfalfa plants that are not part of cropping systems generally have no regular external inputs like irrigation, herbicides, insecticides, and fertilizers; however, alfalfa was

found to survive and increase on rangeland in Utah for more than 10 years, and can reseed on sites with as few as 11 inches (28 cm) of precipitation per year (Sullivan, 1992).

Alfalfa that exists outside of cultivation is typically not targeted for control by herbicide. In some instances on lands where unmanaged or feral alfalfa now occurs, the planting was intentional (e.g., feral plants exist in relegated sown pastures, abandoned alfalfa fields, or on roadsides once sown with alfalfa seed, [Rogan and Fitzpatrick, 2004]). All feral alfalfa in the United States, like alfalfa under cultivation, originated from introduced varieties. Rogan and Fitzpatrick (2004) summarize the extent of feral populations in six major alfalfa-producing States, confirming that minor feral populations do exist in areas where alfalfa seed or forage is produced. In situations where control of feral alfalfa is desired, it can be controlled or discouraged just like cultivated alfalfa using cultural³ or chemical methods (Rogan and Fitzpatrick, 2004).

Sullivan (1992) reviewed alfalfa use for rehabilitation and disturbed sites. Some uses of alfalfa that can lead to feral alfalfa populations are:

- rehabilitation of overgrazed rangelands for improving wildlife habitat and livestock;
- erosion-control projects in interior forests;
- improvements of compacted soils (alfalfa has deep roots that grow vigorously in compacted soils);
- re-vegetation of areas damaged by wildfire (Oregon DFW, 2008); and
- erosion reduction in mined soils (Sullivan, 1992; Withers, 2002).

Survival without management inputs requires feral plants to have traits that may differ from those of cultivated plants. Bagavathiannan and Van Acker (2008) list the following traits that are common among the most successful feral species:

- variety of pollinators,
- continuous seed production,
- considerable seed output,
- seeds produced in several habitats,
- seed dispersal over short and long distances,
- seed dormancy (ability to form a seedbank),
- broad germination requirements,
- discontinuous germination,
- rapid vegetative growth,
- ability to withstand competition,

³ Cultural weed control methods include adding companion crops to the chief crop to smother or suppress weeds, applying a combination of mulches, or crop rotation.

- tolerance to unfavorable biotic and abiotic conditions, and
- rapid flowering.

Alfalfa has many of the above attributes and competes well with other native and introduced plants in a variety of settings. The *M. sativa* subspecies (purple-flowered alfalfa used in cultivation) has naturalized populations in all 50 States, while the *M. sativa* subsp. *falcata* subspecies (yellow-flowered or Siberian alfalfa) is naturalized in the northern and western States and is being promoted as a rangeland enhancer for grazing, as reported in the USDA, Natural Resources Conservation Service (NRCS), National Plant Data Center, PLANTS Database (http://npdc.usda.gov/pdf/0105_npdc_brochure.pdf).

B. Biological Environment at Risk

The terrestrial ecosystems potentially at risk from the application of glyphosate associated with GT alfalfa include the treated area and areas immediately adjacent to the treated area that might receive glyphosate drift or runoff, and might include other cultivated fields, fence rows and hedgerows, meadows, fallow fields or grasslands, woodlands, riparian habitats, or other uncultivated areas. The use of glyphosate is regulated by the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) restrictions administered by the EPA, which mandates registration and use of all pesticides. APHIS has no regulatory authority over the use of glyphosate for any GT crop.

EPA includes instructions and restrictions on how glyphosate herbicides can be applied, and has determined that there is no unreasonable environmental risk if the user adheres to the directions when applying glyphosate herbicide formulations. Directions include application restrictions that minimize impacts on nearby environments. Violators of the regulations are liable for all negative consequences of their actions; therefore, farmers who use glyphosate are very likely to follow its label restrictions, and adverse impacts from the predicted increased glyphosate use will be minimized.

Aquatic ecosystems potentially at risk from glyphosate include water bodies adjacent to, or downstream from, the treated field, and might include impounded bodies such as ponds, lakes and reservoirs, or flowing waterways such as streams or rivers (this discussion is based on the concept that even in the context of FIFRA regulations and label restrictions that are legally required to be followed, there is a chance that glyphosate use might, nonetheless, result in environmental impacts). The proposed use sites may be located either near freshwater or saltwater habitats. For uses in coastal areas, an aquatic habitat also includes marine ecosystems with estuaries.

The above is discussed and reviewed throughout this section.

1. Glyphosate

a. In Roundup® Formulations

The discussion throughout this section is in part taken from the technical report, *Potential Impacts to Wildlife, Amphibians, Plants and Ecosystems from Increased Glyphosate and Other Chemical Usage* (appendix N).

Glyphosate was first introduced as an herbicide under the trade name of Roundup® by Monsanto in 1974. Glyphosate is a systemic, post-emergence herbicide widely used on both agricultural commodities (food uses) and non-agriculture sites (Cerdeira and Duke, 2006). Glyphosate is a substituted glycine, the simplest amino acid. The glyphosate molecule has a methylphosphono group bonded to the nitrogen atom of the amino group of glycine, as denoted in figure 3-1 below.

At normal temperatures, glyphosate is a white crystalline substance that is not volatile (is not likely to vaporize at normal pressure) and is highly soluble in water. Glyphosate salts serve as the source of the active ingredient *N*-(phosphonomethyl) glycine. To improve handling, performance, and concentration, the glyphosate acid is formulated as a salt compound. Several salts of glyphosate are currently marketed. The term acid equivalent (a.e.) refers to the weight of the glyphosate acid, which is herbicidally active, while the term active ingredient (a.i.) is the weight of the glyphosate acid plus the salt. While GT alfalfa could tolerate other herbicides formulated with glyphosate, there are five glyphosate herbicides recommended for use on GT alfalfa. These end use products (EUPs) are presented in table 3-1.

Figure 3-1. Molecular structure of glyphosate.

Table 3-1. Monsanto End Use Products Approved for Use on Glyphosate-Tolerant Alfalfa.

Product Name	% Salt	Glyphosate salt CAS No.	U.S. EPA PC Code	Surfactant	Year
Honcho®	41	Isopropylamine CAS: 38641-94-0	103601	Alkyl Tallow Ethoxylated Amines CAS 61791-26-2	2007b
Honcho Plus®	41	Isopropylamine CAS: 38641-94-0	103601	Trade Secret	2007d
Roundup Original MAX®	48.7	Potassium CAS: 70901-12-1	103613	Trade Secret	2007e
Roundup WeatherMAX®	48.8	Potassium CAS: 70901-12-1	103613	Trade Secret	2007f
Roundup Ultra MAX II®	48.8	Potassium CAS: 70901-12-1	103613	Trade Secret	2004

Glyphosate is a very effective non-selective herbicide (Cerdeira and Duke, 2006). Herbicide formulations in liquid form are generally considered trade secret. One formulation of glyphosate, Honcho®, has a tallow amine surfactant (Monsanto, 2007a). This and other surfactants (surface action agents that are soluble in organic solvents and water), such as polyethoxylated tallowamine (POEA), are added to the herbicide formulations to increase leaf penetration.

The Roundup® Ready Original MAX®, Roundup® WeatherMAX®, and Roundup® Ultra MAX II® products contain 48.8 percent of the phosphate salt of glyphosate, equivalent to 4.5 lbs of glyphosate equivalents per gallon (540 g glyphosate/L). The product is to be applied over-the-top (e.g., spot treatment, broadcast ground application) for pre-plant, preemergence, and post-emergence uses.

Typical single application rates of products containing glyphosate range from less than 1.5 pounds of glyphosate a.e. per acre up to 3.75 pounds of glyphosate a.e. per acre. Application rates were determined using specific product labels for each end use product recommended for use on GT alfalfa (Monsanto, 2007a; 2007f; 2007c; 2007d; 2005b; 2005c; 2004), and are calculated to minimize impact on nearby environments. Application rates of the five end use products recommended for use on GT alfalfa are presented in table 3-2. The maximum use rate (ground or aerial application) for a single application of glyphosate on GT alfalfa is 1.55 pounds of glyphosate a.e. per acre.

Table 3-2. Application Rates of EUPs Recommended for Use on Glyphosate-Tolerant Alfalfa.

Product	Single Use Application Rate	Reference
Honcho®	2.0 lb a.i./acre	Monsanto, 2007a; 2007e
Honcho Plus®	2.0 lb a.i./acre	Monsanto, 2007b; 2007f
Roundup Original MAX®	1.9 lb a.i./acre	Monsanto, 2007c
Roundup WeatherMAX®	1.9 lb a.i./acre	Monsanto, 2007d; 2005a; 2005b
Roundup Ultra MAX II®	1.9 lb a.i./acre	Monsanto 2005c; 2004; 2003

b. Chemical Fate and Transport of Glyphosate in Environment

Glyphosate exposure is possible due to spray drift, inadvertent direct overspray, or wind transport of soil particulates loaded with adsorbed glyphosate. Glyphosate has a low vapor pressure and Henry's law constant; thus, it has a low potential to evaporate from soil and water. Glyphosate is hydrophilic (bonds with and dissolves in water), therefore, it has low potential to accumulate in the tissues of animals. It has a high solubility in water and is not broken down by water (hydrolysis) or by exposure to light (photolysis). Due to glyphosate's strong adsorptive quality with soil (strong ability to collect and remain associated or bound with soil), it is not expected to contaminate groundwater; however, runoff water could contain particulates with adsorbed glyphosate (Giesy et al., 2000).

In soil, sediment, or natural water, glyphosate is primarily broken down by microbes, creating the major metabolic byproduct, aminomethyl phosphonic acid (AMPA). It can be further degraded to CO₂, although at a slower rate than the parent glyphosate (EPA, 1993). In a USDA monitoring study conducted on surface water, groundwater, and soil from 2001 to 2006, the metabolite AMPA was observed more frequently than the parent compound glyphosate (Scribner et al., 2007). The sample collections were from several U.S. Geological Survey (USGS) studies including the National Stream Quality Accounting Network Program; the National Water-Quality Assessment Program; and the Toxic Substances Hydrology Program. EPA determined that, based on toxicological considerations, AMPA need not be regulated (EPA, 2006c).

2. Toxicology and Environmental Risk

The discussion throughout this section is in part taken from the technical report, *Potential Impacts to Wildlife, Amphibians, Plants and Ecosystems from Increased Glyphosate and Other Chemical Usage* (appendix N).

Based on the EPA's toxicological and ecotoxicology and fate databases (EPA, 1993; EPA, 2006a), glyphosate is considered to be a toxicologically and ecologically low-risk herbicide (Cerdeira and Duke, 2006). Based on

the data available on glyphosate usage on GT alfalfa, chemical fate, and toxicity, and after a Tier 1 “high-end use case” scenario screening of hazard quotients, glyphosate is not expected to pose an acute or chronic risk to the following categories of wildlife:

- birds,
- mammals,
- terrestrial invertebrates,
- aquatic invertebrates, and
- fish.

a. Animal Toxicology

(1) Microorganisms and Soil Invertebrates

Microorganisms produce aromatic amino acids through the shikimate pathway, similar to plants. Since glyphosate inhibits this pathway, it could be expected that glyphosate would be toxic to microorganisms. However, field studies show that glyphosate has little effect on soil microorganisms, and, in some cases, field studies have shown an increase in microbial activity due to the presence of glyphosate (USDA–FS, 2003).

(2) Birds

Glyphosate is practically non-toxic to birds and was not found to cause reproductive effects. Toxicity in birds was assessed using single-dose, dietary, and reproductive toxicity studies. Toxicity was assessed by determining dose levels needed to kill 50 percent of a population of test animals. Glyphosate acute toxicity in the Bobwhite quail was slightly toxic. Dietary studies in the Bobwhite quail and Mallard duck are considered slightly toxic for both birds (EPA, 1993; EPA, 2006a). Reproductive studies did not indicate any effect after glyphosate treatment in Mallard duck or Bobwhite quail. Glyphosate tested as acid produced similar results in the Bobwhite quail and Mallard duck; studies with glyphosate tested as its isopropylamine (IPA) salt were not reported for review.

(3) Mammals

In terms of subchronic and chronic toxicity⁴ in rodents, one of the more consistent effects of exposure to glyphosate is loss of body weight. Glyphosate is a Group E carcinogen (cancer-promoting agent) which represents no evidence of carcinogenicity. Additionally, glyphosate does

⁴ Subchronic toxicity studies are those that study the effects on a small percentage of a subject's life span (e.g., up to 10%) while chronic studies continue for a longer period of the subject's lifespan.

not increase the frequency of mutations in an animals' DNA and was not found to cause reproductive or developmental effects in mammals.

Studies with lactating goats, laying hens, rats, rabbits, and cows fed a mixture of glyphosate and AMPA indicate that the primary route of elimination was by excretion (urine and feces).

(4) Amphibians

Glyphosate is slightly toxic to amphibians; however, amphibians exhibited greater sensitivity to Roundup® formulations than to glyphosate tested as an acid or IPA salt. This could be due to the surfactant (POEA) used in agricultural formulations. POEA is a surfactant used in many herbicide formulations (such as GLYFOS®) to increase the ability of active ingredients to penetrate leaf cuticles (Lajmanovich et al., 2003).

(5) Fish

Many studies have also been performed in a variety of species of fish to determine the acute toxicity of glyphosate formulations. In general, the glyphosate formulations (herbicide plus other chemicals) were more toxic to fish than technical glyphosate (herbicide only). The increased toxicity is due to the presence of a surfactant in glyphosate formulations (Giesy et al., 2000).

The most sensitive species to the formulations considered was rainbow trout when treated with formulations similar to Roundup® UltraMAX II® and Roundup® WeatherMAX® (Monsanto, 2004; Monsanto, 2005). In bluegill sunfish, channel catfish, and fathead minnow, formulations of glyphosate are much more toxic than technical grade glyphosate (Giesy et al., 2000). Interestingly, many salmon species studied were less sensitive to glyphosate formulations than to glyphosate.

(6) Terrestrial Invertebrates

Honey bees are the preferred species to assess the toxicity of herbicides on arthropods by EPA. Glyphosate is considered “practically non-toxic” according to EPA standards, based on the toxicity needed to kill 50 percent of the test animals (Giesy et al., 2000; Monsanto, 2005, 2006, 2007b, 2007d).

(7) Aquatic Species

Glyphosate is slightly toxic to aquatic invertebrates, but formulations with certain surfactants are considered very toxic. Several acute and lifecycle toxicity tests have been performed on a variety of fresh water aquatic

invertebrates for glyphosate and various herbicide formulations. The most sensitive species to glyphosate was the buzzermidge (*Chironomus plumosus*). The most sensitive species to glyphosate herbicide end-use formulations was the water flea (*Daphnia magna*). In the case of the water flea, glyphosate formulations are several orders of magnitude more toxic than technical glyphosate.

Per the EPA's 1993 Reregistration Eligibility Decision for Glyphosate, "since there is such an extensive data set for this chemical, the Agency can determine that glyphosate demonstrates low toxicity to fish and oyster species, and therefore is waiving the marine fish and oyster acute⁵ toxicity studies on the formulated product."

The saltwater and marine species tested for toxicity to glyphosate and glyphosate herbicide formulations for GT alfalfa were invertebrates. The most sensitive marine species to glyphosate was the tiny zooplankton, *Acartia tonsa* which is abundant in warm coastal and estuary water.

b. Plant Exposure to Glyphosate

Glyphosate is estimated to be equally toxic to both terrestrial and aquatic plants (USDA, 2003). EPA has evaluated glyphosate's toxicity to aquatic plants based on studies submitted for the registration of the chemical and additional studies are also available (USDA, 2003).

Most plant species, when exposed to glyphosate, experience high levels of toxicity. Vascular plants that use the shikimate pathway to produce aromatic amino acids will experience toxic effects as they metabolize glyphosate. These toxic effects could include the inability to photosynthesize, the inability to complete respiration, and the inability to synthesize nucleic acids. Although the effects can be slow to progress, all of these toxic effects could result in plant death. Spray drift is one of the pathways of concern for non-target plants; if aerial applications are minimized this risk to nontarget plants should be reduced. AMPA, the primary degradation product of glyphosate, seems to be equally or less toxic than glyphosate; therefore, a separate risk characterization was not evaluated (USDA, 2003).

c. Glyphosate Resistance in Weeds

Weeds can develop resistance to herbicides for the following reasons: frequent exposure to a particular herbicide, the spread of naturally resistant weed seeds, and the outcrossing of herbicide-tolerant genes from

⁵ Acute toxicity studies are those that study the effects of a single or short-term exposure to a substance.

plants, either GE plants or plants that naturally have herbicide tolerance genes, to weedy relatives.

Currently, GT weeds are on two million acres of farmland in the United States (Hubbard, 2008). Some of the glyphosate-resistant weeds may also produce copious amounts of seeds, which may lay dormant in the soil and germinate many years later, further compounding the problem of glyphosate-resistant weeds and complicating the containment efforts by farmers relying only on glyphosate for weed control. The most problematic glyphosate-resistant weeds in the United States include pigweed (waterhemp), horseweed (marestail), common and giant ragweed, and ryegrass (Hubbard, 2008).

d. Threatened and Endangered Species

Threatened and endangered (T&E) species occur in the major plant and animal ecosystems, such as terrestrial ecosystems (e.g., meadows, fallow fields, grasslands, woodlands, riparian habitats) and aquatic ecosystems (e.g., lakes, rivers, streams). Those T&E species that may be exposed to the gene product in GT alfalfa would be those T&E species that inhabit alfalfa fields and feed on GT alfalfa (e.g., seeds, leaves, roots) or T&E plant species that are sexually compatible with GT alfalfa.

T&E species may also be exposed to the application of glyphosate-based herbicides associated with GT alfalfa (see discussion in the Biological Impacts section and in appendix N). The species that could potentially be affected by the use of glyphosate on GT alfalfa are any that inhabit the terrestrial and aquatic ecosystems potentially at risk from the application of glyphosate associated with GT alfalfa. In this context, areas that could be potentially at risk include existing and planned GT alfalfa fields, as well as any other areas which may be suitable for GT alfalfa cultivation regardless of current use.

3. Gene Flow

Commercially cultivated alfalfa properly belongs to the *M. sativa* complex, a group of closely related subspecies that are reproductively compatible. The most commonly cultivated alfalfa in the world is *M. sativa* subsp. *sativa*, but subspecies *falcata* is also cultivated on a limited basis, primarily under rangeland conditions and in colder regions (e.g., Canada and Siberia). Other subspecies in the complex include subsp. *glutinosa*, subsp. *coerulea*, subsp. *x tunetana*, subsp. *x varia*, subsp. *x polychroa*, and subsp. *x hemicycla* (Quiros and Bauchan, 1988). Two other closely related species, *M. prostrata* and *M. glomerata*, can be considered capable of limited natural hybridization with alfalfa (Quiros and Bauchan, 1988); however, they do not occur naturally in North America.

Current native populations of members in the *M. sativa* complex to which cultivated alfalfa would hybridize, as well as other perennial *Medicago* species, exist particularly in Europe, Asia, the Middle East, and North Africa (Sinskaya, 1961; Lesins and Lesins, 1979; Ivanov, 1988). Based on a search for *Medicago* populations in the United States, 12 matches were found (see table 3-3) (<http://www.natureserve.org/explorer>). All of the 12 matches were to plants non-native to North America and were either conspecific (belonging to the same species) to *Medicago sativa* (two) or naturally sexually incompatible with *M. sativa* complex (ten).

Table 3-3. Members of the Genus *Medicago* Found in North America as Listed by NatureServe Explorer.

<i>Medicago</i> sp. in North America	Evidence for Natural Hybridization to <i>Medicago sativa</i> Complex	Range of Occurrence
<i>M. arabica</i> Spotted Medicago	No	CAN: BC, NB USA: AL, AR, CA, CT, DC, FL, GA, IL, LA, MA, ME, MO, MS, NC, NJ, OK, OR, PA, RI, SC, TX, VA, VT, WA
<i>M. laciniata</i> Cut-leaf Medicago	No	CAN: ON USA: MA, ME
<i>M. littoralis</i> Water Medicago	No	USA: NJ
<i>M. lupulina</i> Black Medicago	No. Reports of hand-cross hybrids are disputed and discounted as false hybrids by numerous experts.	CAN: AB, BC, MB, NB, NF, NS, ON, PE, QC, SK USA: AK, AL, AR, AZ, CA, CO, CT, DC, DE, FL, GA, HI, IA, ID, IL, IN, KS, KY, LA, MA, MD, ME, MI, MN, MO, MS, MT, NC, ND, NE, NH, NJ, NM, NV, NY, OH, OK, OR, PA, RI, SC, SD, TN, TX, UT, VA, VT, WA, WI, WV, WY
<i>M. minima</i> Small Medicago –grass	No	USA: AL, AR, AZ, CA, CT, FL, HI, KS, LA, MA, MD, MI, MO, NC, NJ, NY, OK, OR, TN, TX, VA, WA
<i>M. monspeliaca</i> Hairy Medicago	No	USA: AL, ME, MD, NY
<i>M. orbicularis</i> Button Medicago	No	CAN: BC, ON USA: AL, CA, FL, GA, IL, LA, MD, MS, NC, NJ, OK, TN, TX
<i>M. polymorpha</i> Toothed Medicago	No	CAN: BC, NB, ON, QC, SK USA: AK, AL, AR, AZ, CA, CT, FL, GA, HI, ID, LA, MA, ME, MI, MO, MS, MT, NC, NE, NJ, NM, NV, NY, OH, OK, OR, PA, RI, SC, TN, TX, UT, VA, VT, WA, WY
<i>M. praecox</i> Mediterranean Medicago	No	USA: CA, MA
<i>M. rugosa</i> Wrinkled Medicago	No. A single hybrid plant was produced via hand-pollination and embryo rescue; no viable progeny produced.	USA: HI
<i>M. sativa</i> Alfalfa	Yes, Conspecific	CAN: AB, BC, MB, NB, NF, NS, ON, PE, QC, SK, YT

<i>Medicago</i> sp. in North America	Evidence for Natural Hybridization to <i>Medicago sativa</i> Complex	Range of Occurrence

Evolutionarily, *M. sativa* is very distantly related to the annual members of *Medicago*. However, *Medicago lupulina* (black medic), an annual (possibly a sometimes short-lived perennial) self-pollinating species, is known to occur throughout the United States and is the species that might be of most concern for hybridization. *M. lupulina* is considered a weed in lawns and waste places, and in forages because its seeds frequently contaminate forage legume seed crops. Successful hybridizations between *M. sativa* and *M. lupulina* have been reported (Southworth, 1928; Fryer, 1930; Schrock, 1943), but the validity of these past crosses has been disputed. According to Quiros and Bauchan (1988) and McCoy and Bingham (1988), no annual species are known to naturally hybridize with *M. sativa*.

Gene flow between alfalfa populations is a natural occurrence and bee-mediated cross-pollination among plants within a cultivar is necessary for commercial seed production. Alfalfa seed producers use spatial isolation to separate cultivars and manage bee and pollen flow between fields of different cultivars. The minimum isolation standard for foundation and certified seed fields more than 5 acres in size is 600 and 50 ft, and for fields 5 acres or less, the standard is 900 and 165 ft, respectively (Association of Official Seed Certifying Agencies (AOSCA), 2003). State seed certifying organizations that are members of AOSCA may adopt the same or more stringent local standards for certified alfalfa seeds. For example, Idaho Crop Improvement Association (2007) requires a greater isolation distance (900 ft) than AOSCA between certified seed fields when one field is conventional and the other is of a genetically modified type (e.g., GT).

In addition to field isolation, certified seed production applies standards for field history, known genetic origin of the stock seed, and in-crop volunteer control to maintain a variety true to type. Variety certification is distinct from organic certification of seeds—variety certification is a product-based certification wherein specified tolerances for off-types and impurities are recognized. USDA organic certification is a process-based certification only; organic seeds or products are not certified according to genetic purity. In a Web search of organic seed suppliers, none were found that offered organically grown seeds of a certified variety. This is discussed in technical report, *Glyphosate-Tolerant Alfalfa Presence in Human Food and Animal Feed* (appendix Q).

Alfalfa plants and alfalfa debris produce compounds that elicit an autotoxic reaction to germinating alfalfa seed. This autotoxic reaction and inter-plant competition severely limits germination and seedling vigor of alfalfa sown or dropped into existing or newly terminated alfalfa stands (Xuan et al., 2005).

4. Alfalfa Consumption by Livestock

Combs and Hartnell (2007) examined the effect of GT alfalfa forage on feed intake, milk composition and milk production in 16 multiparous (cows that than have given birth more than two or more times), lactating Holstein dairy cows. They concluded that milk production, milk composition, feed intake and feed efficiency were not different for dairy cows fed GT versus control alfalfa hay. GT alfalfa hay has also been used as feed extensively without incidence since deregulation in 2005. These results confirm those derived from previously conducted compositional analyses for GT alfalfa, where no differences were observed between GT alfalfa and the control, and further confirm the feed safety of glyphosate and the CP4 EPSPS protein.

C. Socioeconomics

1. Domestic Economic Environment at Risk – Conventional Alfalfa

This section addresses the topics of the economics of conventional (non-GE) alfalfa production and use, the economics of organic alfalfa production and use, the international trade in alfalfa seeds and hay, and the social environment of alfalfa farming and public perceptions regarding organic and genetically modified ingredients in food. The following discussion has come in part from technical reports, *Changes in the Economics of Alfalfa Farming with Deregulation of Glyphosate-Tolerant Alfalfa* (appendix K); *Impacts to United States Trade of Deregulation of Glyphosate-Tolerant Alfalfa* (appendix R); *Economic and Social Impacts to Conventional and Organic Farmers of Deregulation of Glyphosate-Tolerant Alfalfa* (appendix S); and *Downstream Effects to Organic Production and Marketing of Deregulation of Glyphosate-Tolerant Alfalfa* (appendix T).

The economics of conventional (non-organically produced) alfalfa are presented below, broken into discussions of the production and demand for alfalfa hay, alfalfa seed, and alfalfa for human consumption. Each of these has its own particular market and production characteristics.

a. Conventional Alfalfa Farming For Forage

(1) Production of Alfalfa for Forage

The harvested acreage of alfalfa hay (dry) was almost 21 million acres in 2008, generating some 69.6 million tons of hay (including hay mixtures) at an average yield of 3.32 tons per acre (USDA-NASS, 2009). This yield corresponds to almost half the production of all hay that year (approximately 145.6 million tons). Statistics for acreage of alfalfa used as haylage (alfalfa baled at a higher moisture content than dry hay) for all States is only captured in the Agricultural Census; based on the most recent 2007 census and more recent USDA–National Agricultural Statistics Service (NASS) data available on 18 States, haylage acreage likely accounts for an additional 10 to 15 percent of alfalfa acreage grown for forage. Alfalfa is the fourth most common crop by acreage in the United States (USDA-NASS, 2008).

The alfalfa share of total hay production has been falling in recent years, as has absolute production of alfalfa hay (see table 3-5). In 2008, alfalfa production was at its lowest level (69.6 million tons) compared to a high of 84.4 million tons in 1999. Although it is a highly sustainable practice, alfalfa's use in crop rotation is declining in the United States because it demands different management, equipment, market channels, and labor schedules not common to other mainstream cropping systems (USDA-ERS, 2002). In certain locations, livestock to consume the hay may no longer be located in the vicinity, and transportation of the hay may be prohibitively expensive.

Alfalfa is grown for forage in almost all of the States (see figure 3-2), with farming conditions varying considerably depending on climate, rainfall, soil fertility, weed and disease prevalence, whether it is seeded in fall or in spring, for dairy or other use, among other factors. Hower et al., (1999) differentiated between four distinct regions in alfalfa farming: north-central, west, northeast, and south. The north-central region represented the highest acreage of alfalfa followed by the west. Together these two regions had 90 percent of the alfalfa acreage in the country. The west, however, had the highest yields, relatively high prices, the most seeding done in fall and relatively high rates of insecticide and herbicide use (50 percent of alfalfa hay acreage), while the north-central region had the lowest yields, lowest prices, most seeding done in spring and the lowest rates of insecticide and herbicide use (8.1 percent of alfalfa hay acreage).

A study conducted by Rogan and Fitzpatrick (2004) also found that western regions tend to have significantly higher yields than the larger overall acreage of the north-central area.

Hay Production Cost Studies

There have been a number of cost studies done by university cooperative extension services on the production of alfalfa hay and alfalfa haylage. APHIS believes that cost studies from four States—Nevada, Ohio, California, and Wisconsin—capture the costs of production associated with alfalfa hay farming in areas with distinct production challenges. Significant cost components varied in the studies. These studies show regional differences in the costs of inputs, including chemical use which varied from 9 to 22 percent of total operating costs in the cost studies. (Myer et al., 1997; The Ohio State University Extension, 2003). The cost studies did not show the cost of inputs for alfalfa hay production to be as significant a factor for returns as yield and quality.

The Integrated Pest and Crop Management Portal of the University of Wisconsin Plant Sciences outreach programs posts a “Roundup Ready® Alfalfa Calculator” (<http://ipcm.wisc.edu/WCMNews/tabid/53/EntryID/208/Default.aspx>). Table 3-4 shows the results of this calculator for costs of conventional hay in Wisconsin, which includes both establishment and production costs, as presented on the Web site. APHIS extended their analysis to include herbicide costs and the price of alfalfa hay (as discussed in technical report, *Changes in the Economics of Alfalfa Farming with Deregulation of Glyphosate-Tolerant Alfalfa* (appendix K)) and found that while a 40 percent increase in seed costs and herbicide costs have a less than proportional impact on profit, a 40 percent increase in alfalfa hay prices will more than triple the profit per acre. This implies that reductions in the costs of herbicides and seeds are less important in a producer’s choice than the possibility of obtaining higher quality alfalfa hay. As percentage changes in yield also seem to have a high impact on returns, it could be argued that farmers of conventional alfalfa face a trade-off between pursuing higher yields of alfalfa of lower quality, by harvesting a shared alfalfa-weed mix, or pursuing higher prices of alfalfa with lesser weed content.

**Table 3-4. Establishment and Production Cost of Conventional Alfalfa
Units Per Acre.**

Seed cost per 50-lb bag (\$)	\$200.00
Pounds of seed per acre	12
Technology fee per bag (\$/bag)	\$0.00
Yield in seeding year (t/a DM)	3.50
Herbicide cost (\$/acre/application)	\$20.00
Herbicide application cost (\$/acre)	\$10.00
Number of herbicide applications	1
Value of ease of roundup use (\$/acre)	\$0.00
Yield depression from pursuit/raptor (t/a DM)	0.30
Expected stand life (yrs including seeding year)	3
Value of hay (per ton DM)	\$100.00
Fixed costs per acre per year	\$180.00
Harvesting costs per acre per harvest	\$35.00
Number of harvests	2
Seeding Year Production Costs/Results	
Seed cost (prorated + tech fee) per acre *	\$16.00
Total seed and herbicide cost per ton of hay	\$14.38

¹ Based on Long et al. 2007 estimated 12.5% reduction in yield for organic alfalfa production

² Based on an estimated 18% price premium for organic alfalfa

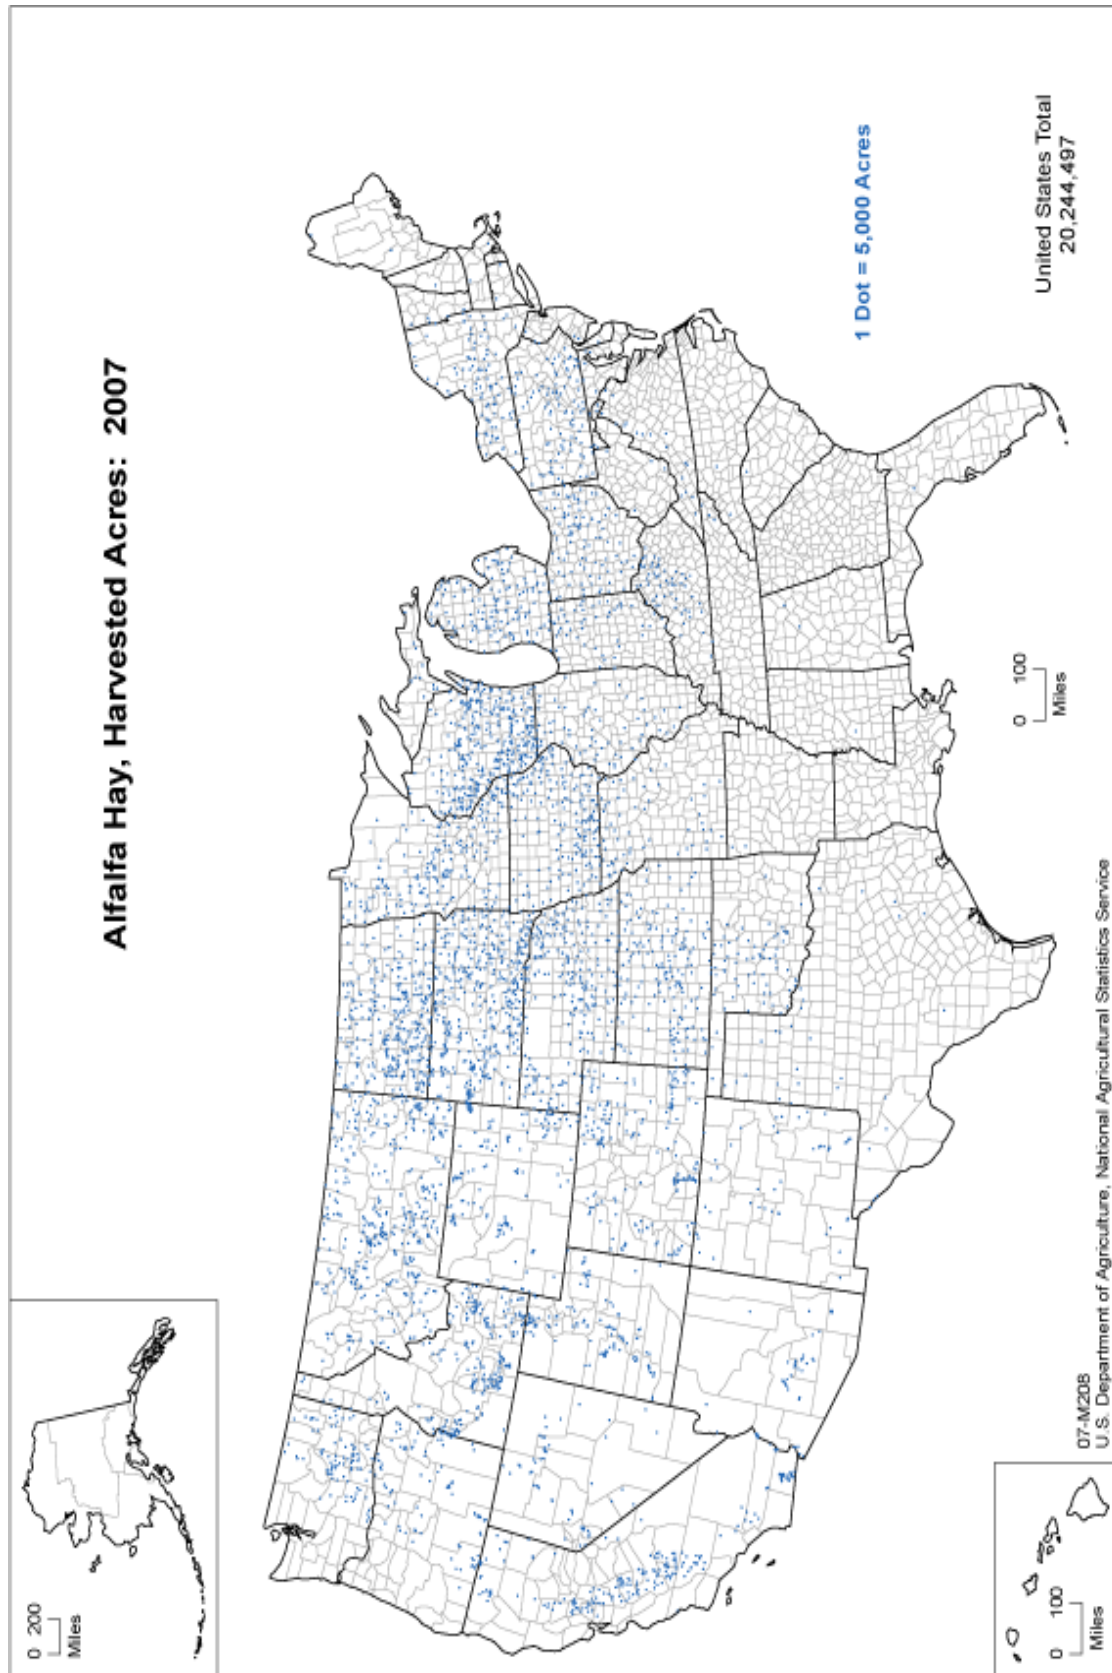

Figure 3-2. Geographic distribution of alfalfa forage acres, 2007 (USDA, 2007).

(2) Demand for Alfalfa Forage

APHIS was unable to locate complete and systematic data on alfalfa forage consumption in the United States (Klonsky et al., 2007); however, an approximate aggregate value of the demand for alfalfa hay can be obtained through production and trade statistics (assuming the accumulation of stored alfalfa hay over time is zero.). USDA–NASS estimates the value of alfalfa hay production in the United States was approximately \$9 billion in 2007. This number was obtained by multiplying average prices with volumes produced and does not correspond to actual sales. Actual sales were likely much less as, according to Klonsky et al. (2007), the majority of the alfalfa hay produced in the United States is produced on farms. This estimate is provided, therefore, for illustrative purposes only.

Discounting for this rough figure of \$9 billion, the \$171 million in alfalfa hay exports (see below for more information on alfalfa exports), and adding \$7 million in imports of alfalfa that occurred that year, the domestic market for alfalfa hay would be approximately \$8.8 billion in 2007. The same reasoning would lead to a domestic market of \$7.5 billion in 2006 and \$7.2 billion in 2005 (see table 3-6).

Table 3-6. Domestic Alfalfa Hay Market (1,000s of Dollars).

Item	2007	2006	2005
Production	8,972,483	7,668,870	7,342,000
Exports	170,925	165,192	165,087
Imports	6,800	3,613	2,430
Consumption	8,808,358	7,507,291	7,179,343

Sources: Production data from USDA NASS (2008a). Trade data from USDA Foreign Agricultural Service (FAS). Consumption calculated as production – exports + imports, and assuming change in alfalfa. Inventories is zero.

* Imports reported as alfalfa bales, not alfalfa hay.

APHIS was unable to find data on the national distribution of the consumption of alfalfa hay among its various uses. Putnam (2005) states that the three main domestic markets for alfalfa are dairy farms, beef farms and horse farms, with minor uses of alfalfa hay “for small ruminants (sheep, goats), alfalfa meal for processed feeds, and alfalfa pellets for pets and rabbits.” Of these, dairy farms are “by far” the main consumer. Klonsky et al. (2007) estimates dairy farms absorb between 75 to 85 percent of alfalfa hay in California, with another 10 to 15 percent consumed by horses and 5 to 10 percent used in the production of beef.

One indication of the role of dairy farms on alfalfa hay consumption can be found by multiplying the number of dairy cows in the United States by an estimate of alfalfa hay intake. Using alfalfa consumption estimates provided in Hoyt (2001) of an intake of 15 pounds of alfalfa hay per day per dairy cow, another 7 pounds a day for milk replacement heifers and another 3 pounds a day for dairy heifers under 500 pounds, and assuming

the proportion between milk cows, milk replacement heifers and heifers under 500 pounds is roughly 4:2:1, APHIS estimates consumption of alfalfa hay for dairy to be approximately 177 million pounds per day, or 32.8 million tons a year.⁶ This corresponds to roughly 46 percent of the domestic market estimated to be at 71.8 million tons in 2007 (72.6 million tons produced, minus exports, plus imports).⁷

The quality of alfalfa hay is determined by the presence of weeds, fiber content, protein content, and other factors such as color and mold presence (Klonsky et al., 2007). USDA's Agricultural Marketing Service uses the grades of supreme, premium, good, fair, and utility to regularly report average prices in various States. They describe each grade as follows:

- Supreme: Very early maturity, pre bloom, soft fine stemmed, extra leafy. Factors indicative of very high nutritive content. Hay is excellent color and free of damage.
- Premium: Early maturity, that is, pre-bloom in legumes and pre head in grass hays, extra leafy and fine stemmed-factors indicative of a high nutritive content. Hay is green and free of damage.
- Good: Early to average maturity, that is, early to mid-bloom in legumes and early head in grass hays, leafy, fine to medium stemmed, free of damage other than slight discoloration.
- Fair: Late maturity, that is, mid to late-bloom in legumes, head-in grass hays, moderate or below leaf content, and generally coarse stemmed. Hay may show light damage.
- Utility: Hay in very late maturity, such as mature seed pods in legumes or mature head in grass hays, coarse stemmed. This category could include hay discounted due to excessive damage and heavy weed content or mold. Defects will be identified in market reports when using this category (USDA-AMS, 2008).

Other sources note that alfalfa hay quality grades differ to some degree from State to State (McWilliams et al., 2005), or speak of high quality alfalfa as being "dairy-quality" (Klonsky et al., 2007). According to Klonsky et al. (2007), there is no clear cut classification for alfalfa hay quality.

Dairy cattle and horses both tend to have high forage quality requirements (Van Deynze et al., 2004). Most weeds are lower in forage quality or palatability (ability to appeal to animals as food) than alfalfa, and forage with high weed content can adversely affect milk production, as well as animal growth and health (Van Deynze et al., 2004). Forage quality

⁶ 9.2 million milk cows in 2007 (USDA ERS, 2008) x 15 lb = 138 million lb
4.6 million replacement heifers x 7 lb = 32.2 million lb
3.2 million heifers under 500 pounds x 3 lb = 9.6 million lb.

⁷ Production data from USDA ERS, 2007. Trade data from USDA FAS (online searchable database). Trade data is available in metric tons, transformed to short tons by multiplying by 1.10231.

requirements for sheep and goats are less rigorous. Beef producers in particular, facing relatively low margins, are apparently a market for lower quality (and cheaper) alfalfa (Klonsky et al., 2007).

Some States provide data on prices of different hay qualities. Table 3-7 below shows some of the historic price differences for different hay qualities in areas of California. The table also illustrates differences in prices depending upon location. As shown, prices can vary by more than 50 percent depending on quality and location. Distinctive regional alfalfa markets likely reflect the importance of transportation costs in limiting the trucking of relatively high volume, low value alfalfa hay across longer distances.

Table 3-7. Price Differences of Hay Qualities (\$/Ton), 10-Year Average, 1997-2006.

Region	Hay Quality Category			
	Supreme	Premium	Good	Fair

(3) Alfalfa Forage as a Downstream Input to Human Food Production

This section briefly describes alfalfa feed as an economic input to its primary industries of use (dairy farms, beef cattle, and horses, with much smaller amounts being used for goat, sheep and small animal feed and other processed feeds).

Dairy Production

USDA estimated production costs for dairy farms in the United States based on the 2005 Agricultural Resources Management Survey (ARMS). According to this data, feed corresponds to 30 to 60 percent of total costs per hundredweight (100 pounds) sold, which includes one-time costs for establishment. The weight of feed on total costs is larger for smaller farms

given the lower productivity and relatively larger overhead. Looking at the share of operational costs (a subset of total costs) feed costs represent, roughly 70 to 85 percent, suggests the price of feed is a major determinant of the cost of dairy production for dairy farms (see table 3-8, below).

Table 3-8. Weight of Feed Costs in Dairy Farms.

Farm Type	Feed Costs/ Operational Costs	Feed Costs/ Total Costs
Conventional United States	73.3%	44.1%
Conventional California	79.7%	57.8%
Conventional Wisconsin	72.0%	40.4%
Conventional < 50 cows	73.4%	30.0%
Conventional 1000 cows or more	83.3%	44.1%
Organic United States	77.8%	41.9%
Organic < 50 cows	76.9%	33.7%
Organic 200 cows or more	79.6%	42.8%

Source: USDA-ERS, 2005

Alfalfa is likely a considerable share of feed costs. Short (2004) reports hay and straw, presumably mostly alfalfa, represents roughly a third of feed costs. Alfalfa may also be used in cubes or pellets. In some regions (Wisconsin, Minnesota) haylage is also a significant share of feed.

Beef Production

USDA-ERS produces cost estimates annually for a variety of farm products. According to the latest estimates available (2005–06), feed corresponds to an average of 56.8 percent of operational costs and 28.8 percent of total costs of cow-calf production (USDA-ERS, updated 2008). Harvested forages correspond to almost half of feed costs (46.9 percent). Other sources report a somewhat lower figure of 35 percent of operational costs and 20.8 percent of operational and ownership costs, with only between 10 to 20 percent of feed costs corresponding to purchased harvested forages (Short, 2001).

Alfalfa is likely a lower share of feed costs in cow-calf production than it is in dairy production since the main source for cow-calf production feed is grazing (Short, 2001). As cattle move on to feedlots (sometime through stocker operators) feed becomes mostly grain based ration.

Other Livestock, Pet Care, and Honey Production

Of the remaining potential sources of demand for alfalfa hay, the most important is horses. Putnam (2005) estimates that horses may consume between 5 to 15 percent of alfalfa hay in California. He also, however, describes the horse market for alfalfa hay as idiosyncratic, subjective, and supplemented by alternative hay such as timothy and grass.

The honey industry utilizes alfalfa fields for honey production. Alfalfa produces a large amount of nectar from which honey bees produce excellent crops of high quality honey (McGregor, 1976). The actual market demand for alfalfa hay fields by beekeepers appears to be small to non-existent; alfalfa seed producers usually contract for the bee keepers' services.

b. Conventional Alfalfa Farming for Seed

(1) Production of Alfalfa for Seed

Unlike alfalfa hay production, alfalfa seed production is largely concentrated both geographically and in the number of producers (see table 3-9). The latest complete information on alfalfa seed production comes from the 2007 Census of Agriculture, when 121,467 acres of alfalfa seed were harvested producing approximately 62 million tons of seeds at an average productivity of approximately 510 lbs/ acre. California was responsible for 31 percent of this production, Washington 17 percent, and Idaho 15 percent, with over 60 percent of production concentrated in those three States and the remaining also highly concentrated in Western States (Nevada, Oregon, Wyoming, Montana, and Utah). Mueller (Undated a) suggests California's share of production has fallen in recent years and a larger share is coming from the Northwestern States. In 2007, production came from 806 farms. This means that farming conditions for alfalfa seed production are likely more homogeneous than alfalfa hay farming. U.S. alfalfa seed growers also compete with their conventional seed producing counterparts in Canada, Australia, and elsewhere, where comparative production costs are significantly lower (e.g., USDA Docket 04-085-1; public comment by M. Wagoner,[December 12, 2004; comment P5]).

Alfalfa seed acreage and production increased between 2002 and 2007, reversing the trend of decreases in alfalfa seed production over the last few years. Similar economic, social, and competitive challenges face both U.S. alfalfa seed and forage growers. Mueller (2008) attributes recent reductions in alfalfa seed acreage in California to "changes in economics, environmental constraints, and regulatory issues." Mueller (Undated a) lists among difficulties of alfalfa seed farming in California scarcity of water for crop irrigation and lack of development of new chemicals for insect control due to high registration costs. However, between 2002 and 2007, California gained almost 10,000 acres of alfalfa seed production.

Some farmers allow existing alfalfa hay stands to go to seed at the end of the stand life or when there is little water. According to Mueller (2005b), this is the case for most of the seed produced in the Imperial Valley (California), about half of the non-certified seed produced in Utah, and

much of the dryland seed produced in Montana. This seed would typically not receive certification.

Despite the mixed purpose of many alfalfa fields that generate seeds, there are clear differences in best practices for managing forage alfalfa and seed alfalfa. Dense stands produce higher forage yields but lesser seed yields than thinner stands, as when alfalfa is planted in rows as opposed to solid planting, and certain chemicals used in seed production limit field use for forage (Mueller, 2008). Alfalfa seed farmers also have some costs that are not present in alfalfa hay farming: some insects are only important for alfalfa seed production (Mueller, Undated a), and costs associated with contracting with bee keepers for pollination services are considerable.

Table 3-9. State Production of Alfalfa Seed (2007 Census of Agriculture).

State	Farms	Seed Acres Harvested	Pounds of Seed Harvested
California	114	36,625	19,083,458
Washington	82	17,127	10,860,608
Idaho	92	12,788	9,346,709
Wyoming	62	10,548	5,915,816
Nevada	19	6,498	4,237,101
Montana	80	10,338	3,729,635
Oregon	32	4,959	3,183,375
Utah	54	3,803	2,077,813
Arizona	53	5,206	1,902,669
South Dakota	47	6,014	428,447
Oklahoma	29	2,004	281,121
Texas	24	546	79,885
Minnesota	17	611	63,461

Michigan	10	(D)	15,610
New York	3	27	6,180
Iowa	5	(D)	(D)
Ohio	1	(D)	(D)
Colorado	8	1,815	(D)

(D): Data withheld to avoid disclosing data for individual farms.

The presence of weeds may have a greater impact on costs in alfalfa seed production compared to alfalfa forage production. The separation of weed seeds from alfalfa seeds after harvesting is costly, so control of weeds in the fields is a more desirable method of seed quality control than post-harvest screening and separation (Mueller, Undated b). No primary or secondary noxious weeds⁸ are allowed for certified seed, with the removal of dodder seed of particular importance (Mueller, 2008). (See section

⁸ Primary noxious weeds cause harm wherever they grow and are an economic issue, while secondary weeds are designated at a local level for additional control.

below on Weeds in Alfalfa for more information on dodder and other alfalfa weeds.)

As discussed in technical report, *Changes in the Economics of Alfalfa Farming with Deregulation of Glyphosate-Tolerant Alfalfa* (appendix K), another important difference between alfalfa hay and alfalfa seed production is that the quality of seeds (germination, yield, dormancy, and other varietal properties) are not readily observable at the moment of purchase. To ensure quality, mechanisms come into place to offer clients (and breeding companies) assurance that seeds sold as one variety or another will perform as expected. State Crop Improvement Associations—or sometimes Seed Grower Associations—(all of these are members of the Association of Official Seed Certifying Agencies) provide certifications that seed production followed minimum standards, such as isolation between different alfalfa varieties, absence of prohibited noxious weeds in the field, inspection of conditioning (separation) facilities, maintaining traceability of seed lots, and seed testing.

Finally, an important cost in seed production is the seed itself. The development of crop varieties became a predominantly private activity in the past 30 years (Fernandez-Cornejo and Schimmelpenninck, 2004) and the Plant Protection Variety Act of the early 1970s simulated cultivar development in alfalfa (Bouton, 1998). Today almost all new alfalfa varieties are owned and patented.

Seed Production Cost Studies

There have been a number of cost studies related to the cost of producing alfalfa seed. The cost studies reviewed for this EIS deal with the economics of alfalfa seed production in three Western States—California, Nevada, and Idaho—due to the geography of seed production. A 1985 cost study found land rental to be the highest cost component (Sheesley, 1985). However, recent cost studies show pollination services (bees) account for the most significant cost component of alfalfa seed production, ranging from 18 to 30 percent of annual production costs. The second most significant cost component found in the recent cost studies was insect control, accounting for between 10 and 17 percent of total annual production costs. (Kettle, Myer and Breazeale, 1999a; Kettle, Myer and Breazeale, 1999b; Meister, 2004; Rimbey et al., 2005). Table 3-10 below shows the main cost items reported, with the last column showing the percentage total that each line item represents of the total costs.

Similar results were found in a 2005 cost study from the University of Idaho (Rimbey et al., 2005). The study assumes a farm with 150 acres of alfalfa seed over a three year period (the life of the stand) and found that pollination accounted for 25.1 percent of the operating costs, followed by

insecticides at 16.5 percent. Irrigation and herbicides are each just below 10 percent of total operating costs.

Table 3-10. Alfalfa Seed Production Costs.

Item	\$ Per Acre	Percent of Total Costs
Irrigation	35.81	7.88%
Insect Control	77.00	16.95%
Pollination	84.00	18.49%
Total Growing Period Costs	196.81	43.32%
Total Harvest Costs	108.18	23.81%
Land Rent	115.00	25.31%
Cash Overhead	34.30	7.55%
Total Cash Overhead Costs	149.30	32.86%
TOTAL CASH COSTS/ACRE	454.29	100.00%

Source: Meister, 2004

(2) Demand for Alfalfa Seed

The demand for alfalfa seed derives from the demand for establishing new stands of alfalfa hay, and to a much lesser extent from the demand for alfalfa products destined for human consumption. As in the case of alfalfa hay, the domestic alfalfa seed market can only be estimated using available data for production, exports and imports. The last year for which complete data is available is 2007, the year of the last Census of Agriculture.

The estimation presented in table 3-11 suggests the domestic demand for alfalfa seeds in 2007 was approximately \$63 million, up from \$52 million in 1997. Imports represented some 64 percent of domestic demand, although it is possible that some of these imports were re-exported.

Table 3-11. Domestic Alfalfa Seed Market (1,000s of Dollars).

	2007	2002	1997
Production	93,173	66,724	104,492
Exports	66,094	25,963	50,372
Imports	36,363	10,864	14,521
Consumption	63,442	51,625	68,641

c. Conventional Alfalfa Farming for Human Use

Some alfalfa seed is used to produce sprouts for human consumption. Seed for sprouting is produced throughout the world, but the major suppliers are in the United States, Canada, and Australia. Approximately 80 million pounds of alfalfa seed are produced each year in the United States. More than 85 percent of that is produced in six Western States—California, Washington, Idaho, Wyoming, Nevada, and Montana. The balance is from Oregon, Arizona, Utah, and other States. The primary market for that seed is planting stock to produce forage to support the livestock industry in the United States and throughout the world. Only a small fraction of the seed produced is used for sprouting (Mueller, Undated).

APHIS was unable to locate any publicly available sales data for alfalfa sprouts. In testimony given in a public meeting convened by the U.S. Department of Health and Human Services' Food and Drug Administration (1998), sprout industry expert Dr. Earl Hauserman noted that as of 1998 there were about 350 sprouters in the United States. He noted that green sprouts (alfalfa, broccoli, clover, mustard, onion, radish, sunflower, and other sprouts) amounted to about \$80 million a year in sales. Mr. Hauserman also stated that alfalfa sprouts account for about 75 to 80 percent of the green sprout market, or \$60 to \$64 million in annual sales. Hauserman stated that U.S. sprouters utilized approximately 125,000 to 150,000 pounds of alfalfa seed a month to produce about 5 to 6 million 4-ounce packages a month. On an annualized basis, Hauserman's testimony would imply that in 1998 alfalfa sprouters purchased 1.5 to 1.8 million pounds of alfalfa seeds, and produced 15 to 18 million pounds of alfalfa sprouts.

Dehydrated alfalfa leaf is commercially available as a dietary supplement in several forms, such as tablets, powders and tea. Alfalfa is also believed by some to be useful as an herbal or homeopathic medicine (Foster and Johnson, 2006). APHIS was unable to locate any publicly available sales data for alfalfa produced for dietary supplements, herbal remedies, or homeopathic medicines. Nelson (2008) reports an estimate that the total U.S. alfalfa supplement market could be satisfied with 10 tons of alfalfa hay production, which could be produced on 1 to 2 acres.

2. Domestic Economic Environment at Risk – Organic Alfalfa

a. Production of Organic Alfalfa for Forage

Between 2000 and 2005, the number of acres in certified organic alfalfa hay production fluctuated slightly, but overall showed an increasing trend. The percentage of total alfalfa hay acres certified as organic per year was between 0.51 to 0.92 percent nationally during this time period (see table 3-12). During 2005 (the most recent year for which certified organic alfalfa acres are reported), there were 204,380 acres in certified organic production, which was approximately 0.92 percent of the U.S. alfalfa dry hay total. Although the organic dairy and livestock industries are growing very rapidly, organic hay alfalfa acres may be growing at a slightly slower rate because many of the organic dairy and livestock producers are allowing more access to non-alfalfa (e.g., grass) organic pastures to avoid the high bloat incidence associated with grazing pure alfalfa. In contrast to conventional hay marketed mainly on forage quality grade, the main selling criterion for organic hay is often its organic status (USDA-AMS-LGMR, 2007).

Table 3-12. Organic Alfalfa Hay Harvested Acreage.

Acreage	2000	2001	2002	2003	2004	2005
Total	113,157	116,608	155,437	135,717	175,260	204,380
Share of Total U.S. Acreage	0.51%	0.49%	0.67%	0.58%	0.81%	0.92%

Source: USDA-ERS, 2005; USDA-NASS, 2007.

Organic alfalfa hay production is similarly distributed geographically to conventional hay. However, production of organic alfalfa hay is a more significant proportion of total alfalfa hay production in some States. In 2005, for example, more than 4 percent of all alfalfa hay acreage in Idaho was organic, compared to just 0.92 percent nationally. Organic alfalfa also seems to be grown in pockets, with 72 percent of organic acreage located in just 6 States—Idaho, Wisconsin, Minnesota, North Dakota, South Dakota, and California (see table 3-13). These 6 States only account for about 41 percent of total U.S. alfalfa acreage.

The increased price per ton of hay received by organic growers is partially offset by a reduction in forage quality (due to increased weeds in the hay) and an approximately 12.5 percent reduction of alfalfa yield per acre (Long et al., 2007).⁹ The 2005 national average yield per acre for alfalfa was 3.39 tons. Based on differences in organic and conventional alfalfa yield from Long et al.(2007), the total estimated U.S. organic hay production in 2005 was about 606,242 tons; the total U.S. production of alfalfa hay in 2005 was approximately 76,149,000 tons. This estimate is approximate, however, and is only presented here for illustrative purposes.

⁹ Estimates of 10 to 20 percent (or more) yield reductions were estimated by D. Putnam and D. Undersander, State Forage Extension Specialists from California and Wisconsin, respectively (Pers. Comm. No date).

Table 3-5 contains a comparison of total estimated U.S. organic and conventional alfalfa yields for 2002 to 2005.

(1) Demand for Organic Alfalfa for Forage

As in the case of non-organic alfalfa for forage, the demand for organic alfalfa derives mainly from the demand for organic dairy and beef (Butler, 2002). To be sold as organic in the United States, alfalfa hay must meet standards established by the Organic Foods Production Act of 1990 and the National Organic Program (NOP) that became effective in 2001. These standards require that organic dairy and meat products come from dairy cows and livestock fed with 100 percent organic feed, with exceptions for vitamin and mineral supplements (USDA-NOP, 2008). As shown in table 3-5 organic alfalfa hay represented 0.92 percent of total alfalfa hay acres harvested in 2005, up from 0.51 percent in 2000.

Prices and quality requirements are significantly different between organic and non-organic alfalfa hay. USDA-NASS reports the average conventional hay crop value (\$/ton); USDA-ERS reports the organic hay acreage but does not, however, report the value of organic hay, and therefore, it must be estimated. It is commonplace for certified organic feedstuffs to sell for a 10 to 30 percent price premium, depending upon demand and local supplies (Long et al., 2005; USDA-AMS-LGMN, 2006). The value-added price per ton for certified organic alfalfa hay is, on average, 18 percent greater than conventional hay. This price premium was calculated by comparing the mean sale prices of conventional and certified organic hay occurring within each sale location, within each forage quality grade and within each USDA hay market sale reporting period during 2006 (raw data was from USDA-AMS-LGMN, 2006). This price premium is generally supported by the University of California's 2007 *Organic Alfalfa Hay* report, which found that prices for organic alfalfa hay vary depending on season, market, and quality, but will be approximately 20 percent greater than prices for conventional hay, and 2007 USDA-AMS data for three counties in California, which found a slightly greater than 20 percent premium for organic alfalfa. The higher prices of organic hay would generally deter conventional livestock producers from using organic alfalfa when not necessary. Table 3-5 shows the value per ton, value per acre, and value added for organic alfalfa hay from 2002 through 2005 using this estimated 18 percent price premium.

Sources: Organic acres—USDA; Economic Research Service, based on information from USDA-accredited State and private organic certifiers; standard practice data from NASS; Most recent year (2005) for which both certified organic and U.S. total alfalfa hay acre data are available for direct comparison.												
** Estimate assumes equivalent yield per acre and equivalent forage quality grade for organic and standard practice hays. 18% price premium estimate based on median hay selling price for organic vs non-organic hays of the same quality group within the same geography of sale (USDA Livestock, Hay & Grain News, 2005 California Annual Hay Report.)												

b. Production of Organic Alfalfa Seed

APHIS was unable to locate data on U.S. organic alfalfa seed production. U.S. organic hay production in 2005 was roughly 0.92 percent of total alfalfa hay production. APHIS expects that stand establishment demand for organic alfalfa seed (expressed as a percentage of total alfalfa seed demand) would likely be in roughly the same proportion. However, for the reasons noted in above (i.e., the NOP-permitted use of non-organically produced seeds and foreign seed imports), the production of organic seed may be somewhat less than this percentage of the total.

(1) Demand for Organic Alfalfa Seeds

Demand for organic alfalfa seeds derives from the demand for organic alfalfa hay, as NOP requires the use of organic seeds to establish organic alfalfa stands (CFR Title 7, §205.204). However, as previously stated an exception is made to this requirement in cases where such seed is unavailable.¹⁰ In these cases, untreated conventional seeds from non-organically managed fields or conventional seeds treated with substances included in the national list of synthetic substances allowed for use in organic crop production are typically allowed.

APHIS was unable to estimate the demand for organic alfalfa seed, due to the lack of data on production of organic alfalfa seed, as well as on the organic seed trade. Some demand likely does exist and may be supplied by either domestic or imported production (imported seeds were approximately 21 percent of total domestic consumption in 2002¹¹). The Organic Materials Review Institute (OMRI), a nonprofit organization managed by the organic industry, reports three suppliers of organic alfalfa seed for forage in its seed database (<http://seeds.omri.org/index.php?dosearch=1&terms=alfalfa&submit=Go>). Some of this seed is imported from Canada. It is also possible that because non-organic seeds are permitted for use in the production of organic alfalfa hay, demand for organic alfalfa seed may remain low.

The main reason reported by organic certifiers to accept farmers' claims that organic seeds were not available was that organic seeds are not "equivalent" to non-organic available seeds in quality (Baker, 2008).¹² This may be an indication of an unfulfilled demand that, given the growth rates in organic alfalfa seed production, may stimulate the development of "equivalent" organic varieties that may now not be available.

¹⁰ This exception is not made for production of organic edible sprouts.

¹¹ Production data for U.S. domestic seed production comes from USDA Census of Agriculture (2002, 1997); Trade data for seed exports comes from USDA Foreign Agricultural Service.

¹² When asked what crop was most often claimed to not have available organic seeds, certifiers identified alfalfa.

(2) Demand for Organic Alfalfa for Human Consumption

Some alfalfa seed is used to produce sprouts for human consumption. Seed for sprouting is produced throughout the world, but the major suppliers are in the United States, Canada, and Australia; only a small fraction of the seed produced is used for sprouting (Mueller, undated). APHIS was unable to locate any publicly available sales data for organic alfalfa sprouts. Using data drawn from the U.S. Department of Health and Human Services' Food and Drug Administration (1998), it is estimated that in 1998 alfalfa sprouters purchased 1.5 to 1.8 million alfalfa seeds, and produced 15 to 18 million pounds of alfalfa sprouts. Presumably, organic sprout production in 1998 was some fraction of total sprout production.

Dehydrated alfalfa leaf is commercially available as a dietary supplement in the form of tablets, powders and tea, and is believed by some to be useful as an herbal or homeopathic medicine (Foster and Johnson, 2006). APHIS was unable to locate any publicly available sales data for alfalfa produced for dietary supplements, herbal remedies, or homeopathic medicines. Nelson (2008) reports an estimate that the total U.S. alfalfa supplement market could be satisfied with 10 tons of alfalfa hay production, which could be produced on 1 to 2 acres.

3. Trade Economics of Conventional and Organic Alfalfa

Certain official statistics for the tonnage of exported alfalfa hay data are highly mixed with and confounded by export statistics for other species crop hays (e.g., USDA-AMS-LGMR, 2007; Woodward, 2006; Putnam, 2005). USDA-FAS (2006) reports estimates for all alfalfa exports, which includes dry hay, cubes, pellets and meal. These hay data are reported by volume (tons), not by acres. Approximately 1.6 percent of the U.S. dry hay crop is exported (table 3-5). Most of this exported hay is grown in Washington and California, where average yield is 4.9 and 6.9 tons per acre, respectively, and relative to the national average, hay value per ton is high. Using the mean hay yield for these two States (5.9 tons per acre), the exported hay represents the equivalent production of approximately 204 thousand acres. It should be noted that an acre producing for the export market during one or more cutting periods likely produces hay for the domestic market at other times of the year (Putnam, 2005) (i.e., fields of alfalfa are not dedicated to the export market per se as they are in organic production). The number of acres from which exported hay is harvested annually is not known (Putnam, 2005).

On average, the FAS-reported selling price of exported hay is approximately \$160 per ton, which is similar to the price for domestically sold hay in the region of production (Pacific Northwest and California). However, using USDA-AMS-LGMN data, in 2006, within grade, within location, within month, the calculated price paid for export alfalfa hay was

approximately 0 to 6 percent lower per ton on average than the price for domestic cattle-use hay of the same grade (calculated from head-to-head comparison of selling prices reported by USDA-AMS-LGMN, 2006). Therefore, in general, export market hay has a similar selling price per ton as other locally available hay; it is not considered a value-added market per se although there is significant value in the ability to contract for a large volume of sales to a few importing customers ahead of harvest time. According to Shewmaker et al. (2006), “The export market helps support and stabilize[s] domestic forage prices in the [Pacific Northwest].” According to a National Alfalfa and Forage Alliance (NAFA) document addressing coexistence in the alfalfa export markets (NAFA, 2007) the export hay market is of key importance to certain producers in Washington, Oregon, and California, and coexistence strategies for minimizing comingling between GT and non-GT alfalfa may be effective (see table 3-14).

Annually, the export hay market is valued at approximately \$192 million (USDA-FAS, 2006) (table 3-5). It may be noted that, in general, hay sold into the export market channel is of “good,” “good/premium,” or “premium grade.” In 2006, no or few “supreme” grade hay lots were exported (USDA-AMS-LGMN, 2007). The highest quality grade hays always are in high demand domestically and locally. The export quality specifications, although affected by objective forage quality grade, can be more sensitive to highly subjective hay attributes (e.g., green color, dirt-free, animal/insect-free) (Putnam, 2005). Approximately three-fourths of U.S. alfalfa hay exports go to Japan each year; other key alfalfa hay export markets include the Republic of Korea (13 to 16 percent), Taiwan (5 to 7 percent), Canada and Mexico (table 3-15, hay exports; Woodward, 2006). More than 85 percent of alfalfa forage exports are hay/compressed bales, with approximately 13 and 1 percent exported as cubes or meal products, respectively (USDA-FAS, 2006).

a. Alfalfa Seed and Forage Farming

4. Social Environment at Risk

The following discussion is taken largely from a Monsanto report, *Impacts of Roundup Ready Alfalfa on Production Practices and Marketing of Alfalfa Seed and Hay* (appendix V).

Along with its primary value as a high quality livestock feed, alfalfa is a valued rotational crop in U.S. agriculture because it improves soil tilth, fertility and structure. It helps mitigate soil erosion and because alfalfa is a legume, successive crops benefit from residual nitrogen in the soil. Although it is a highly sustainable practice, alfalfa's use in crop rotation is declining in the United States because it demands different management, equipment, market channels, and labor schedules not common to other mainstream cropping systems (USDA-ERS, 2002). In addition, livestock to consume the hay may no longer be located in the vicinity. Alfalfa forage-cutting schedules, yield, quality, and persistence are challenged by weather and pests.

In general, alfalfa requires somewhat more complex management and more labor to produce per ton of bulk forage than alternative annual row crops, such as corn silage. This has occurred even though the alternative forage crop used is not as environmentally sustainable, is not as nutritionally complete for livestock, and is not as profitable in the long term for many farm systems. In part, because of several social and

economic reasons, risk-averse producers in much of the United States have reduced the number of acres planted to alfalfa. It may be noted that, in contrast to several alternative feedstuff crops, alfalfa crop prices are not directly managed or insured by government programs. Very little hay is transported cross country and almost none is imported to meet U.S. forage market shortfalls, although dairy and livestock producers require a constant supply. The crop is a perennial that peaks in yield during the second and third year. Relative to annual crops, alfalfa demand and supply are more prone to serious within-season imbalance, price volatility, and the selling price of the alfalfa crop is not known at planting time. Alfalfa growers face the risk of weather interacting with weed competition or herbicide application outcomes that can lead to unpredicted stand failure, stand depletion and or temporary or permanent loss of hay quality or stand yield potential.

In parallel and for several of the same reasons, the numbers of alfalfa seed growers and seed acres have declined in the United States. Most alfalfa seed is grown on highly valued irrigated land in the West where there is much competition for the limited number of skilled growers and suitable acres for alfalfa seed growing. U.S. alfalfa seed growers compete with their conventional seed producing counterparts in Canada, Australia, and elsewhere, where comparative production costs are significantly lower (e.g., USDA Docket 04-085-1; public comment by M. Wagoner [December 12, 2004; comment P5]).

Alfalfa seed yield is highly influenced by grower inputs (such as fertilizer, pesticides, herbicides, and/or irrigation), weeds and insect pests and seasonal weather fluctuations. The cost and availability of required cultured pollinator bees is highly variable (many cultured bees are imported from Western Canada). Similar economic, social, and competitive challenges face both U.S. alfalfa seed and forage growers. Weeds, for example, increase the costs for all alfalfa producers.

b. Consumer Demand and Preferences

(1) The Organic Segment of the Food Industry

The organic sector is rapidly growing both in the European Union (EU) and the United States (Dimitri and Oberholtzer, 2005). Together, consumer purchases in these two regions made up 95 percent of the \$25 billion in estimated world retail sales of organic food products in 2003 (Willer and Geier, 2005). In reporting the results of their annual manufacturer survey, the Organic Trade Association (2007) reports that U.S. organic food sales were estimated to be \$16.67 billion in 2006, up 22 percent from 2005 (see table 3-16).

The Organic Trade Association (2007) notes that organic foods have shown consistent annual growth rates of 15 to 21 percent since 1997, when fairly comprehensive data were first available. Moreover, they report growth rate data based on historical surveys and interviews with long-time participants in the organic foods business in a similar range of nearly 20 percent annually since 1990. Organic food sales are projected to continue growing at a similar pace through 2010 (table 3-16).

Table 3-16. U.S. Organic Food Sales and Sales Growth Forecasts.

Category of Food	Sales (Millions of \$)			Annual Sales Growth Rates (%)		
	2004	2005	2006	2004-2005	2005-2006	Forecasted Annual 2007-2010
Organic Dairy	1,731	2,140	2,668	24	25	20
Organic Meat	195	256	334	31	30	27
All Organic	12,460	13,831	16,673	11	22	18

Source: For 2005-2006, Organic Trade Association Manufacturers Survey (2007); For 2004, Organic Trade Association Manufacturers Survey (2006). Data rounded to the nearest integer value.

Of the total amount of 2006 organic food sales reported by the Organic Trade Association (2007), 16 percent were made up of organic dairy products, while another 2 percent came from organic meat. Moreover, organic dairy product sales in 2006 were reported to represent an increase of 25 percent over 2005 levels. Table 3-16 also provides recent trend sales data for organic meat, indicating an even faster growth rate than organic dairy products, though from a much lower base sales level. The Organic Trade Association (2007) notes that overall consumer purchases of organic foods in 2006 represented only 2.79 percent of total U.S. food sales, though this figure is up from 0.81 percent in 1997. The Organic Trade Association (2008) reports that while organic dairy sales in the United States represented 0.79 percent of all dairy sales in 1997, by 2006 that figure had increased to 4 percent of all dairy sales.

Organic production may be somewhat lagging behind the growth in demand; the Organic Trade Association (2006) indicated that 52 percent of respondent firms reported that a lack of dependable supply of organic raw materials has restricted their company from generating more sales of organic products. Willer et al. (2008) report that agricultural land under organic production systems represented 0.5 percent of all agricultural land in the United States in 2006, somewhat below the worldwide average.

There is evidence that consumer perceptions of organic food safety may be an important driver for consumer substitution of organic for conventionally produced food. In particular, Dimitri and Oberholtzer (2005) argue that changes in organic and conventional food demand are driven in part by “food scares.” They note, for example, that mad cow

disease (bovine spongiform encephalopathy (BSE)) considerably influenced the European organic livestock and dairy industry. Dimitri and Oberholtzer (2005) report that in response to news reports on BSE, many consumers substituted organic dairy and meat products (which consumers perceived as safer) for conventionally raised dairy and meat products. Dimitri and Oberholtzer (2005) report that other food scares that caused European consumers to substitute organic for conventionally produced food include episodes of contaminated chicken feed in Belgium in 1999, feed contaminated by dioxin in 2004, and more recently, carcinogenic food dyes in TV dinners in Ireland in 2005. However, Dimitri and Oberholtzer (2005) do not find evidence that U.S. consumers are as strongly affected by food scares.

(2) Consumer Sensitivity to GE Content in Food

Demand for GE foods or for foods free of GE content is very difficult to estimate. In the case of European countries this is because most European major food retailers do not carry GE foods in response to consumer concerns (Noussair et al., 2004). In the case of the United States, the absence of mandatory labeling for GE foods makes demand estimation difficult. Most U.S. consumers are unaware of the prevalence of GE material in the U.S. food supply (Anderson et al., 2006; Hallman and Hebden, 2005; Thomson and Dininni, 2005). Hallman et al. (2003) found that only one-fourth of U.S. residents believed that they had ever consumed food containing GE ingredients. There seems to be no estimate available of consumer demand for GE-free food products (Noussair et al., 2004).

However, in the last decade, there have been a considerable number of attempts to identify consumer preferences regarding GE foods, in and outside the United States, most of them based on consumer surveys done under various conditions asking consumers to express their preferences under hypothetical situations. The results overwhelmingly show lack of information regarding GE foods and some resistance towards their consumption (Hallman and Aquino, 2003).

A number of studies have implemented experiments in which consumers actually get to choose among products and benefit from their choices. Lusk et al. (2004) developed a meta analysis of 25 studies including 57 valuations of GE foods. Most of the studies analyzed are from the United States, a third are from Europe, and the remainder are from Asia, Canada and Australia. Seventeen of the studies are based on consumer surveys while 8 are based on experiments. These studies report that the willingness to pay for GE-free foods was positive, implying that consumers were willing to pay more for these foods.

A number of other studies have investigated whether the resistance to GE foods and the lack of information regarding biotechnology are correlated. Chern and Rickertsen (2002) conducted a student survey in four countries (United States, Japan, Norway and Taiwan) and a national phone survey in the United States and Norway. Willingness to consume GE foods increased when it was explained that GE foods could include benefits such as the reduced use of pesticides. Bertolini et al. (2003) compared attitudes towards GE foods in the United States, Japan, and Italy in random surveys of food shoppers. They also found a positive impact of familiarity with GE technology on acceptance. On the other hand, Hallman and Aquino (2003) conducted a survey of a random sample of U.S. households and found out that improved information on GE food did not necessarily mean increased approval. Those most knowledgeable of GE material tended to have more extreme opinions, in favor or against, than those less knowledgeable. Noussair et al. (2004) also found that prior beliefs regarding GE food had a stronger influence on consumer choice than information.

Studies also exist investigating how consumers value varying levels of GE content in their foods. In an experiment in France, where consumer surveys reveal very strong resistance to GE products, Noussair et al. (2004) found that 89 percent of consumers were willing to purchase a product with up to 1 percent GE content and 96 percent with up to 0.1 percent GE content. They also found that consumers differentiated between GE-free and 0.1 percent of GE-content. On the other hand, a nationwide study in the United Kingdom found that consumers did not distinguish between 0 and 0.5 percent GE levels in food and did not place a value in having products with 0 percent GE content as opposed to 0.5 percent (Rigby et al., 2004).

In response to consumer concerns, over 40 countries have adopted labeling regulations for GE products (Guère et al., 2007).¹³ In Europe, the main impact of labeling requirements has been the virtual disappearance of many GE products, given that the cost differentials in production are small (since often GE ingredients are a minor share of total ingredients in products) and the risk of loss of market share is high given the perceived consumer resistance (Guère et al., 2007). In addition, to the extent that labeling requirements require segregation of GE and non-GE products throughout the production process, labeling may imply considerable costs (Noussair et al., 2004).

United States

There is relatively little literature specifically assessing purchase motivations associated with GE foods in the United States. In their

¹³ Some of these regulations have not yet been implemented or only partially so.

summary of 25 valuation studies relating to GE food, Lusk and Rozan (2005) found that U.S. consumers are more receptive to GE foods than their European counterparts, although a preference for non-GE foods remains, suggested by various estimates of willingness to pay for GE-free foods.

Lusk and Rozan (2005) attribute differences in GE product receptivity by consumers in France and the United States, partially to differences in information about GE foods and partially to different levels of trust in the sources providing information. While the United States showed greater knowledge of GE foods, there was also greater trust in the institutions delivering the information (food regulatory agencies, universities, agribusiness).

There is some evidence that consumers support genetic engineering for use in crops to a greater extent than in animals from which dairy, meat, and other food products derive (Ganiere et al., 2006). Hallman et al. (2003) reported that one-half of U.S. residents surveyed approved of plant-based genetic engineering, while only one-quarter approved of it for use in animal agriculture. In fact, the survey by Lusk et al. (2003) found that consumers in the United States were more averse to hormone use than use of GE animal feed. Several studies have argued that even with the negative opinions Americans express about biotechnology in surveys, there has been little apparent effect on sales of food items that contain or are raised on GE ingredients or feeds (Fernandez-Cornejo and Caswell, 2006; Putnam, 2005).

In the case of organic foods, one of the unique attributes of organic foods, and one reason consumer demand for organic foods is increasing, is the intended absence of GE ingredients in the process of producing them (Anderson et al., 2006; Dhar and Foltz, 2005; Larue et al., 2004). USDA-NOP standards currently require that goods labeled “100 percent organic” must be produced and handled without the use of excluded methods, one of which is the form of genetic engineering used to produce GT alfalfa cultivars. Livestock standards applied to animals used for meat, milk, eggs, and other animal products call for animals to be fed 100 percent organic feed, with vitamin and mineral supplements excepted (USDA-NOP, 2008). At the present time, there is no policy regarding the unintended presence of GE material in organic products or food, consistent with the fact that the NOP is a process-based program for certifying a farm or production system as organic, and not a product-based program that tests or certifies individual products as organic.

D. Human Health and Safety

1. Risk from Gene Product

The U.S. Food and Drug Administration (FDA), the lead U.S. regulatory agency for review of the food and feed safety of GE crops, completed a voluntary consultation with Monsanto and FGI in 2004 regarding the safety of GT alfalfa (FDA, 2004b). FDA concluded that the CP4 EPSPS protein produced by GT alfalfa lines J101 and J163 was biochemically and functionally equivalent to CP4 EPSPSs produced by other Roundup Ready® crops, and to the family of EPSPS proteins that naturally occur in crops and microbiologically-based processing agents that have a long history of safe consumption by humans and animals. Specifically, FDA (2004b) made the following assertions: the soil bacterium used to create GT alfalfa is not a known allergen or pathogen (does not cause allergic reactions or diseases); the CP4 EPSPS gene and protein lack structural similarities to any allergen (it does not have the same structure as anything that causes allergic reactions); the CP4 EPSPS protein is only a small portion of alfalfa; and while acute toxicity in mice was observed, allergenic responses associated with Roundup Ready® crops have not been reported by farm workers or members of the general population since the commercialization of these crops in 1996. FDA (2004b) did not review studies on dermal or inhalation toxicity of the CP4 EPSPS gene or protein, nor were any available at the time of this analysis. Reviews on the nutritional quality of GE foods conclude that there is no significant nutritional difference in conventional versus GE plants for food or animal feed (Flachowsky et al., 2005).

2. Risk from Glyphosate and Other Herbicide Use

Herbicides used in conventional alfalfa farming can be divided into two major groups—herbicides that do not kill alfalfa and can be used to control weeds in alfalfa (2,4-DB, benefin, bromonoxynil, clethodim, diuron, EPTC, hexazinone, imazamox, imazethapyr, metribuzin, norfluzon, paraquat, pronamide, sethoxydim, terbacil, and trifluralin), and herbicides that kill alfalfa (2,4-D, dicamba, clopyralid, glyphosate, and picloram) and are used for alfalfa stand removal. Although more recent figures are not reported, in 1998 a University of Wisconsin weed control specialist reported that herbicides are applied to less than 17 percent of U.S. alfalfa hay acreage (Wilke, 1998).

A controversy exists over whether herbicide use overall has increased as a result of GT crops initially adopted in 1996. A few studies have claimed that the volume of herbicide use is greater due to GT crops (Benbrook, 2004), while other studies demonstrate a decrease on overall herbicide usage related to the increased use of herbicide resistant crops (Fernandez-Cornejo, 2006; Gianessi and Reigner, 2006; Sakula, 2006; Johnson et al., 2008; Hiemlich et al., 2000). Benbrook (2004) evaluated USDA-NASS data on GE crop acreage along with data on pesticide volumes used, from 1996 to 2004, and determined that GE corn, soybeans, and cotton have led

to a 138 million pound increase in herbicide use since 1996, which is a 5 percent increase. GT corn also shows a trend for increasing use of non-glyphosate herbicides, from 42 percent of acreage in 2002 to 55 percent of acreage in 2006. Benbrook (2004) attributes this increase to increasing weed resistance to glyphosate and reduction in glyphosate prices after the patent expired. Benbrook (2004) concluded that across all crops, genetically modified crops reduced pesticide use from 1996 to 1998, but from 1999 to 2004, pesticide use increased.

Others have indicated there has not been a significant increase in the amount of herbicide usage since the advent of GT crops. They noted that using glyphosate has resulted in the replacement of herbicides that are at least three times as toxic and persist almost twice as long as glyphosate, (Gianessi and Carpenter, 2000). Trewavas and Leaver (2001) conducted an analysis which revealed that 3.27 million kg of other herbicides have been replaced with 2.45 million kg of glyphosate in soybean fields in the United States. Carpenter and Gianessi (2003) concluded that the introduction of GT soybeans has resulted in a decrease in the total volume of herbicides used.

Gianessi and Reigner (2006) noted that an increase in glyphosate usage coincided with a decrease in total amount of herbicide usage by 61 million pounds (of active ingredient) between 1997 and 2002. Much of this reduction occurred in cotton and soybeans, where several herbicides were replaced by glyphosate. Johnson et al. (2008) evaluated the USDA-NASS database and concluded that herbicide use in 2006 was reduced by 100.5 million pounds of active ingredient, based on estimates of biotechnology-derived crop replacement of conventional crops.

Other studies showed a decrease in the overall amount of herbicide applied to herbicide-tolerant crops. For example, Sankula (2006) evaluated the impact of biotechnology-derived crops planted in the United States in 2005 and determined the following:

- Herbicide-tolerant canola used less herbicide active ingredient per acre than conventional canola, which represented a reduction of 0.69 million pounds of herbicide use in 2005.
- Herbicide-tolerant corn reduced herbicide use in corn by 21.8 million pounds in 2005, which corresponds to a grower cost savings of \$269 million. Compared to 2004, grower returns were 94 percent higher and pesticide use was 18 percent lower due to a 67 percent increase in the adoption of herbicide resistant corn (due to EU approvals).
- Herbicide-tolerant cotton reduced pesticide use by 18 million pounds and reduced production costs by \$39 million.

- On average, GT soybean programs used 1.03 pounds active ingredient per acre (lbs a.i./A) whereas conventional herbicide programs used an additional 0.32 lb a.i./A. This translates to a reduction of 39.4 million pounds of herbicide and a cost savings of \$134 million.

a. Glyphosate Toxicity

Glyphosate is among the most widely used pesticides by volume in the United States. While additional glyphosate products may be used, five products are recommended for use on GT alfalfa. The five herbicides are Monsanto products and include: Honcho®, Honcho Plus®, Roundup Original MAX®, Roundup WeatherMAX®, and Roundup Ultra MAX II®. Glyphosate products can be formulated to have different concentrations of glyphosate acid per gallon of product. However, in general, glyphosate is more environmentally and toxicologically benign than many of the herbicides that it replaces (Brookes and Barfoot, 2006).

APHIS has no regulatory authority over the use of glyphosate, and has no authority to restrict or otherwise regulate the amount of glyphosate that is used in the environment. That authority belongs to the EPA, pursuant to FIFRA.

The concern, for risk assessment purposes, is glyphosate residue and glyphosate's only known metabolite, aminomethylphosphonate (AMPA), which is not included in either the tolerance expression or the risk assessment (EPA, 2006). Although AMPA is a common environmental metabolite, only trace amounts of it are formed in mammals, with the remainder being excreted unchanged. For this reason, direct exposures to AMPA, as an endogenous metabolite in animals, are encompassed by the existing toxicity data on glyphosate.

Glyphosate acts on various enzyme systems and inhibits amino acid metabolism of EPSPS in plants. This enzyme is absent in mammals. "Glyphosate is particularly effective because most plants metabolically degrade it very slowly or not at all, and it translocates well to metabolically active tissues such as meristems" (Cerdeira and Duke, 2006). Based on EPA's toxicological, ecotoxicology, and fate databases, (EPA, 1993; EPA, 2006a) glyphosate is considered to be a toxicologically and ecologically low-risk herbicide (Cerdeira and Duke, 2006).

According to the Reregistration Eligibility Decision (RED) document for glyphosate (EPA, 1993), glyphosate is of relatively low oral and dermal acute toxicity to humans. For this reason, glyphosate has been assigned to Toxicity Categories III and IV for these effects (i.e., Toxicity Category I indicates the highest degree of acute toxicity, and Category IV the lowest). An acute inhalation study was waived by EPA because glyphosate is a

non-volatile solid and the studies conducted on the end-use product formulation are considered sufficient. With regard to subchronic and chronic toxicity, one of the more consistent effects of exposure to glyphosate is loss of body weight. Other general and non-specific signs of toxicity from subchronic and chronic exposure to glyphosate include changes in liver weight, blood chemistry (may suggest mild liver toxicity), liver pathology, and weight of the pituitary gland (USDA-FS, 2003). Glyphosate is not considered a carcinogen; it has been classified by EPA as a Group E carcinogen (evidence of non-carcinogenicity for humans) (EPA, 1993; EPA, 2006).

Various formulations of glyphosate contain POEA at a level of up to approximately 20 percent (200 g/L). Tallow contains a variety of fatty acids (e.g., oleic, palmitic, stearic, myristic, and linoleic acids), as well as smaller amounts of cholesterol, arachidonic, elaidic, and vaccenic acids. While surfactants are typically classified as “inert” components in herbicides, they are not toxicologically inert and in many cases they are found to be more toxic than the herbicide itself (USDA-FS, 2003).

Steckel et al. (2007) evaluated GT alfalfa for 3 years following glyphosate treatments ranging from 0.75 to 3 pounds of acid equivalent per acre (lbs a.e./acre) for crop injury and feed quality. Levels up to 9 lb a.e./acre over 3 years did not cause a reduction in yield or nutrition of the alfalfa in any of the forage quality measurements taken (e.g., protein, starch, sugar).

(1) Risk to Field Workers

There are two types of worker exposure scenarios. The first is the general worker scenario in which workers have chronic dermal exposure to glyphosate via one of three typical pesticide application methods: directed foliar, broadcast foliar, or aerial. An accidental exposure scenario was assessed as the second type of worker exposure scenario. This includes the two most likely types of accident scenarios—spills on arms and spills on legs. Based on conservative hazard estimates, workers in both types of exposure scenarios are not at risk of adverse health effects associated with acute or chronic dermal exposure to glyphosate. (Please see technical report, *Health and Safety Risks for Field Workers*, appendix M.)

(2) Risk to Public Health and Safety

Although the general public is not at a high risk of exposure to substantial levels of glyphosate under typical conditions (EPA, 1993; USDA-FS, 2003), the majority of exposures to glyphosate that may occur are via the oral and dermal route. The general public may be exposed to herbicides used on glyphosate-tolerant alfalfa if they consume crops that were grown near GT alfalfa fields. According to experimental studies, glyphosate is

not completely absorbed when administered orally. Much of the reviewed literature has revealed that only about 30 percent of glyphosate is absorbed from the gastrointestinal tract after oral exposure (USDA-FS, 2003). Furthermore, studies indicate that the majority of unabsorbed glyphosate remains in the gastrointestinal tract, while the absorbed glyphosate is widely distributed throughout the body (USDA-FS, 2003). The highest concentrations of glyphosate are found in the bone relative to other tissues, although glyphosate does not significantly concentrate or persist in any tissue (EPA, 1993).

Glyphosate is also poorly absorbed through the skin, according to two dermal absorption studies performed by Wester et al. (1991, 1996). In general, formulations contain more of the POEA surfactant than the active ingredient, glyphosate. The results of a USDA study (USDA-FS, 2003) indicated that glyphosate containing more of the POEA surfactant (i.e., the undiluted formulation) did not absorb more rapidly than a glyphosate formulation with a less concentrated solution of surfactant.

An APHIS review of health analyses conducted on infants, adults, and the elderly concludes that the majority of the population (analyzed under central and lower exposure estimates) is not at risk of adverse health effects associated with acute exposure to glyphosate (USDA, 2008). Based on upper estimates of exposure, however, infants consuming fruit and all age groups consuming vegetables may be at risk of adverse effects associated with acute exposure to glyphosate residues. The upper estimates of risk are based on highly conservative fruit and vegetable intake rates; thus it is anticipated that only a very small number of individuals will have this magnitude of exposure and therefore be at this level of risk. (Please see technical report, *Health and Safety Risks from Increased Glyphosate and Other Chemical Usage on Humans (Exclusive of Field Workers)*, appendix L.)

b. Other Herbicides

As discussed in the technical report, *Potential Impacts to Wildlife, Amphibians, Plants and Ecosystems from Increased Glyphosate and Other Chemical Usage* (appendix N), the 20 other herbicides used on alfalfa have varying chemical fates. In general, most were more persistent than glyphosate and were characterized by higher mobility in soils, making them more apt to continually contaminate surrounding water systems. Few were even considered compounds that could bioaccumulate, or accumulate in the tissues of plants and animals (e.g., clopyralid, EPTC, norfluzon, sethoxydim, and trifluralin).

Herbicides are used at three different phases in conventional alfalfa farming—stand establishment (to prepare ground), established stands (to

control weeds), and during stand removal (to kill alfalfa). The 16 herbicides that may be used for weed control in conventional alfalfa farming are summarized in appendix G. After 2 to 8 years alfalfa stands are usually thinning and vulnerable to weeds, so the stand is removed by killing the alfalfa by either plowing, herbicide application, or both (Rogan and Fitzpatrick, 2004). Herbicides that are used for stand removal or to control volunteer alfalfa (including GT alfalfa, except for glyphosate) include (Dillehay and Curran, 2006; Miller et al., 2006; Renz, 2007; Rogan and Fitzpatrick, 2004):

- 2,4-D,
- clopyralid,
- dicamba,
- dicamba and diflufenzopyr,
- glufosinate,
- glyphosate,
- primsulfuron-methyl,
- mixtures of dicamba, 2,4-D, and clopyralid,
- picloram,
- picloram and 2,4-D,
- halsulfuron and dicamba,
- acetochlor,
- acetochlor and atrazine,
- acetochlor and atrazine and dicamba,
- atrazine and dicamba, and
- clopyralid and flumetsulam.

Because GT Alfalfa cannot be removed using glyphosate, other herbicides are needed for alfalfa stand removal in GT stands. These herbicides are presented in table 3-17 along with their Environmental Impact Quotient (EIQ).

The EIQ metric was devised in 1992 and gives an indication of the effect of an herbicide on the environment in general (Kovach et al., 1992). It is calculated from a host of parameters and is the average of the farm worker, consumer and ecological components. For comparison, Glyphosate has an EIQ of 15.3, the lowest of the alfalfa-related herbicides in table 3-17.

Table 3-17. Calculated EIQs for Alfalfa-Related Herbicides.

Herbicide	EIQ
2,4-D	18.67
Atrazine (Atrazine)	22.9
Clpyralid (Stinger)	18.1
Dicamba (Dicamba)	28.0
Diflufenzopyr (Distinct)	17.5
Glufosinate-ammonium (Rely)	28.25
Glyphosate (Roundup®)	15.3
Halsulfuron methyl (Sanda)	17.0
Picloram (Pathway)	18.0
Primsulfuron-methyl (Beacon)	27.33

E. Land Use and Production Practices

Alfalfa is grown for forage, grazing, seed production (forage and sprouts), human consumption, and honey production. The most acreage is for dry hay forage, as discussed in chapter 3.C.1.. In the 2 years that GT alfalfa was on the market, ~200,000 acres were planted in 1,552 counties and 48 States with the exception of Alaska and Hawaii. In March of 2007 USDA published notice in the *Federal Register* that GT alfalfa is a regulated article and GT alfalfa seed sales and plantings were halted. GT alfalfa planted in the 2005 and 2006 growing seasons is still permitted to be harvested, but has court ordered stewardship practices to minimize potential of GT alfalfa being present in harvests of non-GT alfalfa harvests (Hubbard, 2008).

The following discussion comes in part from technical reports, *Effects of Glyphosate-Resistant Weeds in Agricultural Systems*, appendix G; *Effects of Changes in Farming Practices on Water, Soil and Air Due to Use of Glyphosate-Tolerant Alfalfa*, appendix J; and *Glyphosate-Tolerant Alfalfa Presence in Human Food and Animal Feed*, appendix Q.

1. Alfalfa Production Practices

Exact alfalfa production practices vary by location, season, and farmer preference, but in general, most alfalfa is sown in the spring, except in the western United States where fall planting is more common (Hower et al., 1999). Alfalfa can be sown anytime there is available moisture and a sufficient growth period for the seedling that is frost-free (about 6 to 8 weeks). Weeds are the most damaging pest during early stand establishment, especially for spring-sown alfalfa.

Based on an extensive survey¹⁴ performed from 1988 to 1992, herbicides are used much more often with seed fields (78.3 percent of total fields)

¹⁴ Data collected in the herbicide survey represented 90.1% of the 25.6 million acres produced annually from 1988-1992 as reported by the NASS.

than with hay fields (16.6 percent of total fields; 22 percent of acreage) (Hower et al., 1999). Mechanical and cultural methods for weed control (e.g., tillage and companion crops) were used for ~80 percent of the spring planted alfalfa and 18 percent of the fall planted alfalfa (Hower et al., 1999).

a. Seed

The following discussion comes in part from technical reports, *Effects of Glyphosate-Tolerant Weeds in Agricultural Systems*, appendix G; *Effects of Changes in Farming Practices on Water, Soil and Air Due to Use of Glyphosate-Tolerant Alfalfa*, appendix J; and *Glyphosate-Tolerant Alfalfa Presence in Human Food and Animal Feed* (appendix Q).

Nearly all alfalfa seed is used for the establishment of hay fields, with a minor amount used as seed field stock seed (variety increase) or for sprouting purposes. Alfalfa seed is not consumed as a grain and, therefore, not used directly as a food or feed product. Essentially all alfalfa planting seed produced in the United States is grown using insecticides and/or herbicides, the use of which precludes the seeds' use for food or sprouting purposes. The use of biologically contaminated canal waters, waste waters, or livestock manures to fertilize alfalfa sprout seed fields are also prohibited by food safety regulations. Therefore seed products for planting and sprouting are kept distinct from each other.

Bass et al. (1988) estimated that 7 percent of U.S. alfalfa seed is used for sprouting, but this has not been confirmed. Acreage or production of sprout-destined seed is not reported and field locations for such production are not recorded, therefore, they are not known officially. It is believed that most of the sprout seeds are imported because economic alfalfa seed production in the United States generally requires the use of some food-prohibited practices.

Alfalfa seed production occurs exclusively in niche areas of the Western United States on approximately 100 to 120 thousand acres under intensive management and irrigated field conditions (see table 3-9). Alfalfa seed production requires a long growing season with a very warm temperature, very low humidity during seed ripening, and specialized equipment. Most professional seed producers use cultured bees and specialized equipment associated with bee culture.

As seen in table 3-9, within the seed producing states seed production is localized to certain counties. In the most recent USDA-NASS Census of Agriculture (2007), during 2002 and 2007, 1,234 and 806 farmers grew alfalfa seed on 110.6 and 120 thousand acres, respectively. This is a small number of growers in comparison to those growing alfalfa for forage (i.e.,

344,000 and 290,000 alfalfa hay growers in 2002 and 2007, respectively). During 2007, 90 percent of the U.S. seed crop tonnage was grown by 304 seed growers operating farms with at least 100 acres of alfalfa seed (USDA-NASS, 2009). Therefore, most of the alfalfa seed production is managed by a relatively small number of large professional seed producers. Nearly all large growers have at least one proprietary seed production contract with one of the four national alfalfa seed production companies.

Cultural practices used to produce seed are distinct from those used to produce forage. Professional seed growers usually grow seed under terms of a two or three year term seed company contract, by variety name. The contracting seed company supplies the stock seed (e.g., foundation seed) to the seed producer and the genetic source variety of the seed is documented. In contrast, seed companies purchasing or growing “common seed” or “catch crop” seed typically use lower management and inputs, the genetic identity of the stock seed is often unspecified /unknown and the resultant product quality is highly variable and cannot be certified as to cultivar or variety identity.

Typically, seed fields are planted in the fall and clipped back in late spring so that bloom within the field is uniform, synchronous and optimally timed for the warm dry season and optimal pollinator activity. Weed and in-crop volunteer controls (herbicides and cultivation) are applied mainly prior to the start of pollination or after seed harvest. Flowering begins in approximately mid June. Insecticides (primarily for *Lygus* control) and other pesticides are applied prior to bee release to avoid insecticide damage to the bees. At approximately 50 percent flower (early to mid July), cultured bees are gradually moved into the seed field for pollination with their domicile or hive for local shelter. The field is actively pollinated for approximately one month, allowed to ripen seed for approximately 4 weeks more, and then, chemically desiccated or swathed several days prior to combining the seed. At the end of the pollination period and just prior to desiccation, the pollinating generation of bees is either at the end of their lifecycle (i.e., leafcutter or alkali bees), or are transported by the honeybee keeper to a different location to forage on fall-flowering plant species. Seed is harvested in mid August to late September depending on geography. In long-growing season regions, the cool-season alfalfa forage growth between seed crops is sometimes mechanically harvested or grazed.

Usually, stands of alfalfa grown for seed production only are maintained for an average of three production seasons. Seed production contracts and AOSCA variety certification standards generally predetermine the length of the seed stand. Because most seed production is planted in widely spaced rows and are not cut monthly, relative to forage stands, weeds in

seed fields have more time and open area to proliferate and compete with the alfalfa. Therefore, weeds, insects, and pests are intensively managed in seed production systems. Weed seeds and weed debris in grower seed lots directly reduce the purity and yield of alfalfa seed and drive up growers' costs to remove them.

b. Forage

Due to climate and other differences, farming practices differ regionally. However, some farming characteristics are shared among growing regions. Alfalfa stands have two growing phases, establishment of seedlings (first year) and established alfalfa fields (two to eight years). Weed management differs for each phase (Orloff et al., 1997). Well-established alfalfa that is not thinning has fewer weeds because established alfalfa is a good competitor. Alfalfa is typically harvested (mowed) every 22 to 40 days depending on growth conditions in the region, local weather patterns, and alfalfa variety. In most of the growing regions, alfalfa is only cut three to four times a year, but in the Southwestern United States, growers can cut up to 10 or 11 times per year (Putnam et al., 2001).

To determine when to harvest, farmers balance yield and nutritional content. Yield increases as plants grow and peaks at 100 percent bloom, but nutritional content is highest in young vegetative plants and decreases until full flower. There is no optimal harvest schedule, because farmers make different decisions based on changing market demand. Farmers typically harvest between late bud stage and full bloom. The highest quality hay (bud stage) is generally used for active dairy cows, whereas, hay that is lower in protein and higher in fiber is fed to beef cattle, horses, heifers (too young to milk) and non-lactating dairy cows (Ball et al., n.d.). Alfalfa for livestock feed can be stored in a variety of forms:

- hay—dry baled at 18-20 percent moisture;
- haylage—round bale silage, baled at 50-60 percent moisture, wrapped in plastic; and
- silage—chopped and blown into a silo or a truck.

Alfalfa grown for hay is sometimes grown with a companion crop to act as weed control and to prevent soil erosion. These crops, such as oats, spring wheat or peas, tend to grow much quicker than alfalfa, and out-compete any weeds while alfalfa is becoming established. Once the companion crop begins to compete with the alfalfa for nutrients, water, and space, the companion crop can be harvested, and serves as extra profit for the farmer (Smith et al., 1998). At this point, the alfalfa is established enough to compete against any weeds on its own. Oats are the most popular companion crop to alfalfa because they are the least competitive, with alternatives such as peas also in wide use, but exact companion crop habits

depend on farmer preference and region (McCordick et al., 2008; Smith et al., 1998). Studies have found that companion cropping in alfalfa can suppress weed growth more than herbicide treatments, but that the crop then competes with the alfalfa, reducing yield (McCordick et al., 2008).

Companion crops are different from nurse crops in that nurse crops are a specific type of companion crop. Nurse crops do not compete with alfalfa for nutrients, but rather are removed or killed with herbicide early in development. This can result in both effective weed control and little impact on alfalfa yield (McCordick et al., 2008). Nurse crops can also help reduce wind, water and soil erosion and provide early groundcover like other companion crops (Hall, 2004). Other types of companion cropping include using a cover crop, used during dormant seasons to protect the soil, or a barrier crop, used as pest management strategy by serving as a refuge and distraction for pests.

2. Alfalfa Farming Practices

Alfalfa farming practices are broken into three categories: organic, conventional, and GT alfalfa.

a. Organic Farming

Organic production includes only those cropping systems that fall under the USDA-NOP definition of organic farming and are certified organic production systems. In organic systems, the use of synthetic pesticides, fertilizers, and genetically engineered crops is strictly limited. A list of NOP approved substances for organic farming inputs can be found on the USDA Web site (<http://www.ams.usda.gov/AMSV1.0/>). Neither glyphosate nor GT alfalfa is permitted in organic systems.

In organic systems, where herbicides are not permitted, the area to be seeded with alfalfa is tilled for weed management and allowed to sit for seven to ten days. Two or more passes to turn the soil with discs may be necessary if weed germination is observed. It is recommended that the field be treated with nutrients, such as compost and boron, and left for a week to check for further weed germination. Further, composted manure fertilizer can be used to kill weed seeds (Canevari et al., 2007). Planting may occur once weed growth potential is minimized (Guerena and Sullivan, 2003).

According to USDA-NOP standards, the following inputs can be used as herbicides or weed barriers, as applicable, to control weeds¹⁵: 1) soap-based herbicides for use in farmstead maintenance (roadways, ditches, right of ways, building perimeters) and ornamental crops; 2) mulches-newspaper or other recycled paper, without glossy or colored inks; plastic

¹⁵ Insecticides and substances to control plant diseases are also included on the NOP list, but are not listed here because they are beyond the scope of this Report.

mulch and covers (petroleum-based other than polyvinyl chloride (PVC)) (<http://www.ams.usda.gov/AMSV1.0/getfile?dDocName=STELPRDC5068682&acct=nopgeninfo>).

b. Conventional Farming

Conventional farming includes any farming system where synthetic (manufactured) pesticides or fertilizers are used. The definition of conventional farming usually includes the use of GE crops, but genetically engineered GT alfalfa is considered separately for this report (Harker et al., 2005). Conventional farming covers a broad scope of farming practices, ranging from farmers who only occasionally use synthetic pesticides and fertilizers to those farmers whose harvest depends on regular pesticide and fertilizer inputs. The 16 herbicides that may be used in conventional alfalfa farming are discussed in *Effects of Glyphosate-Resistant Weeds in Agricultural Systems* (appendix G; table 2-1) (based on OMAFRA, 2008; Canevari et al., 2007; Rogan and Fitzpatrick, 2004; Loux et al., 2007).

c. GT Farming

GT alfalfa can be integrated into conventional farming practices. Farming GT alfalfa is mostly the same as farming conventional alfalfa, with two important exceptions:

- (1) Weeds can be controlled by the application of glyphosate directly on top of growing alfalfa;
- (2) When alfalfa stands reach the end of their life cycle, typically after 3 to 8 years depending on growing region, glyphosate cannot be used to kill the stand to prepare for another rotation (Miller et al., 2006).

In GT alfalfa, herbicides other than glyphosate combined with tillage are required to obtain 100 percent removal. Several of the recommended GT alfalfa stand removal herbicides result in restrictions regarding what crops can be planted next, so careful crop rotation plans are necessary when using GT alfalfa (Miller et al., 2006).

Another important difference is that non-GT crops cannot be used as companion crops for GT alfalfa. This difference is important for farmers that traditionally interseed companion crops like small grains (e.g., oats) with alfalfa; it does not affect farmers that plant pure alfalfa stands. Companion crops may possibly benefit stand establishment by weed control, increased forage yield during the seedling year, and wind and frost protection for young alfalfa seedlings (Orloff et al., 1997). However, it is important to carefully monitor the seeding rates to avoid excessive competition of companion crops with the alfalfa. Companion crops can

increase overall forage yield but may decrease hay quality (McCordick et al., 2008).

3. Weeds in Alfalfa

The following discussion is based in part on the technical report, *Effects of Glyphosate-Resistant Weeds in Agricultural Systems* (appendix G).

Healthy, productive stands of alfalfa require attention to manage pests (including weeds), fertilizer inputs, irrigation (if applicable), and harvest timing. Weeds can be a problem in alfalfa, but once alfalfa is established, it acts as a suppressor of weeds and is commonly used in rotations for weed reduction. For example, prior rotation in alfalfa can reduce weed densities in sunflower to the same level as herbicide treatment and alfalfa in corn rotations has also been observed to benefit corn yield and suppress weeds (Clay and Aguilar, 1998).

Several years after sowing when plants weaken and stands become thin, weeds become more competitive with the alfalfa and can contribute to a significant decline in alfalfa yield and forage value. Well-established alfalfa fields or fields undergoing stand renovation are sometimes used for the disposal of livestock manures. Weed seeds present in livestock manure can contribute to an accumulation of weed seeds in the soil and weed problems in alfalfa production systems. Certain weed species found in alfalfa stands are particularly difficult to control (Hower et al., 1999), are poisonous to livestock, negatively affect palatably or livestock performance, impart off flavors to milk products, and may be noxious regulated species (e.g., dodder).

Farmers are concerned about glyphosate-resistant weeds (Johnson and Gibson, 2006). One hundred and twenty-nine weeds are known to infest alfalfa, some of which have already shown glyphosate resistance. Since 1998, nine new GT weeds have been found in the United States. Eight out of the 14 new GT weeds known globally are also known to be weeds in alfalfa stands. At least 21 weeds that have natural resistance to glyphosate exist. Ten of these naturally glyphosate-resistant weeds are known to be a problem in alfalfa. See *Effects of Glyphosate-Resistant Weeds in Agricultural Systems* (appendix G; table 4.1) for a list of weeds that are known to be glyphosate resistant in general or have glyphosate resistant biotypes, both since 1998 and historically.

Weeds are controlled in conventional alfalfa with chemicals (herbicides), cultural methods (rotation, mowing, companion crops, monitoring), and mechanical methods (tillage). The cultural and mechanical methods are permitted for organic farmers. GT systems allow for the use of one additional herbicide, glyphosate.

a. New Glyphosate-Resistant Weeds

Glyphosate-resistant biotypes have recently been identified for the following eight weeds that are also common in alfalfa: common ragweed, horseweed, Italian ryegrass, Johnsongrass, Palmer Amaranth, buckhorn plantain, goosegrass, and junglerice. (*Effects of Glyphosate-Resistant Weeds in Agricultural Systems* (appendix G; section 4.1.1) briefly discusses each.)

b. Traditionally Glyphosate-Resistant Weeds

Ten weeds that are common in alfalfa and historically have some resistance for glyphosate include bermudagrass, burning nettle, cheeseweed, common lambsquarters, field bindweed, filaree, large crabgrass, morningglory, nutsedge, and purslane. (*Effects of Glyphosate-Resistant Weeds in Agricultural Systems* (appendix G; section 4.1.2) briefly discusses each.)

c. Weed Management Options

Weed management strategies in organic alfalfa systems, conventional alfalfa systems, and glyphosate-tolerant alfalfa systems differ. Management options for conventional systems include (Nandula et al., 2005; Guerená and Sullivan, 2003):

- Chemical (see appendix G; table G-6)
 - Alternating herbicides with different modes of action
 - Tank mixing herbicides
 - Sequences of herbicides
 - Application timing
- Cultural
 - Rotation between GT cultivars and non-GT cultivars
 - Winter crops in rotation
 - Mowing
 - Companion crops/co-cultivation/interseeding/nurse crop)
 - Cover crops (smother crops) (prior to planting alfalfa)
 - Field scouting for early detection
 - Monitor for weed species and population shifts
 - Mechanical
 - Tillage cultivation

Cutting intervals affect weed infestation. For example, if alfalfa is cut too frequently (20 to 25 days) there is not enough time for roots to build up a sufficient storage of carbohydrates so growth after cutting is not vigorous enough and weeds have a competitive advantage. However, sometimes early harvest can rescue a heavily weed-infested new stand if the weeds

are beyond the stage of successful herbicide treatment (Canevari et al., 2007). Alternating long and short intervals between cuttings enables alfalfa to maintain root reserves so plants can recover from defoliation quickly and more vigorously compete with weeds (Canevari et al., 2007).

Crop rotations can help maintain soil fertility, reduce soil erosion, avoid pathogen and pest buildup, adapt to weather changes, avoid allelopathic effects (effects to reduce the growth of one plant due to chemicals released by another) and increase profits (Peel, 1998). Alfalfa is also used in crop rotation because it provides nitrogen to the soil, which decreases fertilizer inputs in other rotations. It can be economically advantageous to include alfalfa in rotations (Mends and Dobbs, 1991). Perennials and annuals promote and restrict different weeds, so rotating perennials with annuals helps control weeds in general. It is also advisable to rotate alfalfa because mature alfalfa is autotoxic to seedling alfalfa (Xuan et al., 2005). Monsanto recommends that alfalfa can be rotated to grass crops (corn and cereal crops) or broadleaf crops, and that alfalfa should not be rotated with other GT crops (Monsanto, 2008). This limits some options for farmers, as GT corn and GT soybean are both popular rotation crops for alfalfa. Typical rotation crops include wheat, oats, barley, potato (*Solanum tuberosum* L.), sugar beet (*Beta vulgaris* L.), and corn. Appropriate weed management practices reduce the probability of weeds developing glyphosate resistance (Rogan and Fitzpatrick, 2004).

d. Distribution of Glyphosate-Resistant Weeds

Table 3-18 shows that currently 19 U.S. States are affected by glyphosate-resistant weeds. The majority of new glyphosate-resistant weeds are located in the Southeast and Midwest. The overlap with the major alfalfa producing states in the Intermountain regions seems to be minimal at this point (see also table 3-20).

Table 3-18. Glyphosate-Resistant Weed Infestations by State.

State	Weed species	~ Number of Sites in State Infested	~ Number of Acres in State Infested	Situation	Year Reported
Arkansas	<i>Conyza canadensis</i> Horseweed	6-10 increasing	1,001-10,000 increasing	Cotton	2003
	<i>Ambrosia artemisiifolia</i> Common Ragweed	1	11-50	Soybean	2004

4. Crop Rotation in Alfalfa

For weed, insect, and disease management, it is recommended that alfalfa be used in rotation with other crops. It is also advised to rotate alfalfa because mature alfalfa produces allelochemicals which are autotoxic to seedling alfalfa. Autotoxicity is the primary problem for alfalfa seeded after alfalfa.

Table 3-19 presents rotation recommendations for control of several common alfalfa pests.

Table 3-19. Recommended Rotations for Pest Reduction.

Pest	Recommended Rotation
Root knot nematode	1 year rotation with cotton
Stem nematode	3-4 year rotation with small grains, beans, cotton, corn, sorghum, lettuce, carrots, tomatoes, or forage grasses.*
Disease Bacterial wilt Anthracnose Spring blackstem Common leafspot Stagonospora	3-4 year rotation with small grains, beans, corn, sorghum, forage grasses.*
Winter weeds	A minimum of 1 year (preferably longer) in crops such as small grains, wheat, oats, winter forage grasses that allow the use of selective herbicides that are not registered in alfalfa.
Summer weeds	A minimum of 1 year (preferably longer) in crops such as small grains, beans, cotton, corn, sorghum, summer forage grasses that allow the use of selective herbicides that are not registered in alfalfa.
Dodder	At least 2 years with cotton or other nonhost crops such as small grains, beans, corn, sorghum, or forage grasses. Avoid rotations with crops such as tomatoes, onions, and carrots that also serve as a host for this weed.
Nutsedge	Two year rotation with corn or sorghum rotation that includes application of herbicide to control nutsedge.

* Three to four-year rotations give satisfactory results. A rotation for fewer years will provide minimal suppression.

Source: Goodell, 2006

The major regional differences for growing alfalfa forage are due to different climatic regions and the adaptation of different varieties to these climatic regions. The major factors involved in variety adaptation are winter temperatures and rainfall. The areas of alfalfa adaptation for the United States are shown in figure 3-3. These regions are recognized by the USDA–Plant Variety Protection Office and the National Alfalfa and Miscellaneous Legume Variety Review Board (Rogan and Fitzpatrick, 2004).

5. Regional Differences in Production Practices

The adaptation of alfalfa varieties to winter temperatures is based on their winterhardiness, which ranges from very dormant and more winterhardy to extremely non-dormant and less winterhardy (Teuber et al., 1998; Rogan and Fitzpatrick, 2004). Dormancy is a condition where physiological activities associated with growth temporarily cease. For alfalfa, dormancy is thought to be brought on by shorter day length and possibly colder temperatures in the autumn. The alfalfa plants reverse this

process in the spring with the onset of warmer temperatures and longer day lengths. The more dormant varieties require numerically more and warmer days along with longer day lengths for vigorous growth to begin again. In regions where winter temperatures are less severe and the length of the growing season increases, the need for winterhardiness decreases resulting in more harvests per year and increased yields per acre per year (Rogan and Fitzpatrick, 2004).

Rainfall influences soil moisture, soil pH, and humidity, which in turn, affects the prevalence of disease, weed, nematode, and insect problems. Therefore, throughout the 1900's, many alfalfa varieties were first developed with varying levels of winterhardiness, and then later for resistance levels to various diseases, insects and nematodes (Melton et al., 1988).

Figure 3-3. Areas of alfalfa adaptation in the United States (Rogan and Fitzpatrick, 2004).

a. Seed Production

Most of the high quality alfalfa seed is grown under irrigation in the western states as noted in tables 3-13 and 3-20 with California, Washington, and Idaho being the top three seed production States. Small acreage seed growers located mainly in the Plains primarily produce uncertified seeds (e.g., for the past several years, South Dakota Crop Improvement has not certified any alfalfa seed production although much alfalfa seed is produced). Overall, approximately 8 and 58 percent of the dormant and non-dormant seed crops are exported, respectively (table 3-18). The States that export the most nondormant and dormant alfalfa variety seeds are California and Idaho (table 3-20).

b. Forage Production

The north-central region has the most acres devoted to alfalfa forage production, followed by the east-central region and the intermountain region. The least amount of forage production occurs in the southeast region. Less than 1 percent of alfalfa hay produced is exported. Nearly 100 percent of exported alfalfa hay is produced in the Pacific Northwest and Southwest regions.

As a percentage of acres produced, the north-central, east-central and southeast regions use most of the hay on the same farm on which it is grown. For the southwest and Pacific Northwest, most of the forage sold is used for dairy farms (USDA-NASS, 2002). (See tables 3-20, 3-21 and 3-22 for more details on forage production.)

c. Weediness and Weed Control

Weeds and their control have a major impact on the management practices in alfalfa seed and forage production. Weed control measures vary by farm within a region as much as among regions. The plant species that are considered weeds in alfalfa production are also affected by the different climates in which alfalfa is grown; thus, different weeds can be expected to vary in their importance in the different alfalfa growing regions. Since each herbicide has a fairly definite array of weeds that it can control without causing major damage to the alfalfa, the use of the different herbicides varies among the regions. Herbicide use depends on the weeds that are causing the most concern on each farm, stage of growth of alfalfa and weeds, potential damage to the crop, forage versus seed production, the potential carry-over for injuring the following crop in their crop rotation, as well as the price-value relationship of each herbicide.

Because alfalfa seedlings grow slowly, they are especially susceptible to weed competition, especially in the spring (Peters and Linscott, 1988; Hower et al., 1999). Extension weed specialists and forage specialists indicate that the best weed control in an established stand of alfalfa is achieved by establishing and maintaining a dense healthy stand of alfalfa. Important factors in establishing a dense healthy stand include proper soil fertility and pH, seedbed preparation, varietal selection, appropriate cutting schedules, insect control and good weed control in the seeding year (Undersander et al., 2004). Stringent weed control during the first 60 days after alfalfa emergence is critical for high quality forage from first harvest, and to prevent stand loss due to early weed competition (Leep et al., 2003). The use of companion crops, such as oats, depends on the relative competitiveness/tolerance to competition of the companion crop plants, alfalfa seedlings, and the weeds. These attributes of competitiveness and tolerance to competition are greatly affected by the appropriate soil

fertility, seed bed preparation, moisture availability and timing of clippings/harvests.

Tillage practices during cultivation of crops impact the soil and water, and can influence such factors as weed control, crop rotations and yields. Tillage is most often used between crops in order to remove the traces of the previous crop and as weed control in preparation for the next crop. Excessive tillage causes soil erosion, but reducing tillage through use of herbicide improves soil nutrients, increases moisture content, benefits soil microbes, decreases runoff, and reduces atmospheric pollutants (Fawcett and Towery, 2002).

Perennial weed species in forage crops become an increasing problem without tillage (Peters and Linscott, 1988). Dandelions, plantain, cinquefoils, docks and thistle species are among the perennials infesting alfalfa (Peters and Linscott, 1988). Other perennial weed problems in alfalfa are quackgrass, nutsedges, white cockle, yellow rocket, Johnsongrass, and bermudagrass.

The cultural methods used to control weeds in the seedling year are clipping, companion crop, flash grazing (where fields are briefly and heavily stocked with grazing animals), and early harvest for spring seeding and fall seeding, with one exception. Early harvest was not noted for fall seeding (Hower et al., 1999). Mowing or cutting is performed frequently (3-10 cuttings per year) in alfalfa as a natural part of the harvesting process. Multiple cuttings for hay harvest each year, for several consecutive years, will impact the weed population and species present in alfalfa. Mowing is beneficial in preventing weed seed production and further infestations, such as annual broadleaf weeds in new alfalfa stands or weeds such as Canada thistle and Johnsongrass in established stands of alfalfa (Peters and Linscott, 1988). Annual grasses cannot be controlled effectively by mowing because growth is regenerated from crown buds near the soil surface below the point of mowing, and mowing is not effective for controlling quackgrass because of its growth patterns.

For organic alfalfa hay growers, these cultural methods are still the only means of controlling or reducing weeds in alfalfa hay fields. For organic alfalfa seed growers (none of which have been identified to date in the United States), insecticides, fungicides, and herbicides cannot be used. The use of these chemicals can increase the harvest of economically viable yields of alfalfa seed, and therefore this lack of pesticide use in organic crops could be a contributing reason for the scarcity of organic alfalfa seed produced in the United States.

d. Seeding and Harvesting

Good establishment is required for a long-lived productive stand of alfalfa. Seeding failures can be the result of poor seedbed preparation, seeding too deep, low moisture availability, freezing, diseases, insects, excess competition for light and nutrients from other alfalfa seedlings, companion crop or weeds, damage from herbicides or insecticides, and excess straw from the companion crop. For seeding, slight differences may be in the equipment used (some farmers may use drills, while others may broadcast the seed and some may even aerial broadcast). Seeding time during the year varies from region to region (the far northern areas will generally seed in the spring to avoid major freezing damage of young seedling plants whereas other areas will seed in the fall), but recommended seeding times are based as much on the previous crop and soil water availability throughout the year as on time of year. The recommended soil preparations are very similar in all regions unless no till planting is used and no-till planting can be used in all regions. For fertilizing, any differences that occur are in the composition of the fertilizer used because of the different soil types in the different regions, but all of the regions generally recommend good availability of phosphorus and potassium. Nitrogen fertilizer is generally not recommended unless considerable refuse from the previous crop exists.

Alfalfa grown for forage can be used for grazing or harvested as silage or hay. Different equipment is used for each type of harvesting. The only major difference for harvests among regions is the total number of harvests per year, with the far northern regions having up to two to three harvests per year due to a shorter growing season than the southern regions, which can have six or more harvests per year. The major differences are in the adaptation of different varieties to the different climates in the United States, and differing levels of various pests (weeds, diseases and insects), which have effects on the pesticides that might be used.

6. Distribution and Acreage (by State and County)

The number and location of alfalfa forage acres are closely associated with livestock operations, especially dairy. In the United States in 2008, approximately 21 million acres were grown for forage production (figure 3-2). The alfalfa acreage in the United States has declined gradually over the past 40 years from a high of approximately 30 million acres (Rogan and Fitzpatrick, 2004).

Table 3-20 summarizes 2006 total hay (and seed) acreage as the sum of “alfalfa dry hay” and “alfalfa hay and haylage” categories, and presents acreage and yield per acre summaries by region and state. Multi-year national statistics for conventional, organic and exported alfalfa dry hay acres and values are presented in table 3.5 for the 4-year period from 2002

to 2005.¹⁶ During the period 2002 to 2006, the number of conventional acres grown for alfalfa forage was relatively stable, with an average of 3.33 tons dry hay per acre

Alfalfa seeds of each variety type are grown in their respective area of adaptation: dormant varieties in the north and, non-and semi-dormant varieties in the southwest, especially California (tables 3-9, 3-13, and 3-20). According to USDA-NASS statistics for 2006, 122 thousand acres were harvested for alfalfa seed, total production was 72 million pounds, and the average yield was approximately 590 lbs per acre (weighted average) (table 3-20).

Table 3-21 presents the U.S. states in order of percentage of alfalfa harvest (in 2005). For each state, the growing region, the percentage of the total national harvest of all alfalfa are presented for 2002, 2005, and 2007; and the percentage of the national organic certified harvest are presented for 2002 and 2005. In 2005, the most recent USDA organic harvest report, 22,439,000 acres of dry hay alfalfa were harvested and 204,380 (0.9 percent) of those acres were certified organic. The number of acres harvested in a state does not indicate the quantity of the harvest. For example, as shown in table 3-22, because of the growing season length, California ranks top in production (in 2007, ~11 percent of the national harvest and ~7 million pounds) and South Dakota ranks second (in 2007, ~6.8 percent of the national harvest and ~4 million pounds) even though South Dakota has ~2 million acres and California has less than 1 million acres of alfalfa. In addition, even though the northeastern states rank low in the percentage of acres and quantity of harvest, alfalfa is the number one crop for several of those states (NAFA, 2007).

Table 3-21. Alfalfa Growing Regions and Percentage of Dry Hay Harvest by State.

State	Growing Region	Percent of harvest acres			Percent of organic harvest	
		2002	2005	2007	2002	2005
South Dakota	North Central	10.57	10.70	9.86	8.58	6.82
Montana	Winter Hardy Intermountain	6.76	7.80	9.23	3.66	2.60
North Dakota	North Central	6.13	7.35	7.20	11.22	10.09
Wisconsin	North Central	7.32	6.91	7.50	16.34	14.38
Minnesota	North Central	5.59	6.02	4.67	6.40	10.44
Iowa	North Central	5.16	5.57	4.10	6.11	4.50
Nebraska	North Central	5.92	5.57	5.36	2.71	4.01
Idaho	PNW-Intermountain	4.57	5.08	5.12	24.69	24.22

¹⁶ 2005 is the most recent year for which organic alfalfa acreage data is available from USDA. Therefore, 2005 is used as the year of comparison for the relative size of organic, export and domestic markets. Dry hay values are used in table 3-21 because exported hay is dried before sale or processing.

State	Growing Region	Percent of harvest acres			Percent of organic harvest	
		2002	2005	2007	2002	2005

D = data withheld to protect identity of individual farms

Source:

http://www.agcensus.usda.gov/Publications/2002/Volume_1,_Chapter_2_US_State_Level/st99_2_026_026.pdf

Other differences in alfalfa farming are revealed by examining the number of farms that grow alfalfa and the number of farms that irrigate. Comparison of California and Wisconsin (table 3-22) shows that in California ~97 percent of the farms irrigate, whereas in Wisconsin only 0.5 percent of the farms irrigate. Farmers that irrigate can maintain soil moisture at near optimum levels and can withhold irrigation before harvesting, giving farmers greater control of harvest timing (Orloff et al.,

1997). In areas where irrigation is uncommon, farmers rely on rain, which has natural variations that greatly influence alfalfa growth and the harvest schedule.

Another difference is farm size. The average farm size in California is much larger than in Wisconsin. It should be noted that the average farm size calculation is a bit misleading because in California some very large farms (4,000 acres) skew the average. In general, because farm size does not fit a normal distribution, the average farm size does not give an accurate picture of farm sizes. However, average farm size does relay the general trend of farm size in a state. Like any census, these data may not include all alfalfa farms.

G. Physical Environment

1. Soils

Like other legumes, alfalfa forms a symbiotic relationship with the nitrogen-fixing bacterium *Sinorhizobium meliloti*. The result is the conversion of atmospheric nitrogen to fixed nitrogen in the soil, resulting in a net increase in available nitrogen to the soil (USDA-FS, 2003).

Studies show that glyphosate does not move deep into the soil, does not get transported at high levels to or through groundwater, and does not persist long in the soil (Major, 2003; Milleret al., 1995; Torstensson, 2005). It is highly adsorptive and remains in the soil until mineralizing bacteria breaks it down; the primary route of degradation (Gimsing et al., 2004). The major byproduct of this process is aminomethyl phosphonic acid (AMPA), which further degrades in the soil to form carbon dioxide. Soil composition does have an effect on glyphosate adsorption, with presence of minerals increasing adsorption (lessening movement of the glyphosate) and the presence of soil organic matter inhibiting adsorption (Getenga and Kengara, 2004; Vereecken, 2005). See section 'Glyphosate' above for details on glyphosate chemical fate and transport in the environment.

2. Climate and Air Quality

Herbicides can pollute air either through drift, the movement of herbicide through the air to unintended sites or evaporation into the air (volatility). Glyphosate is essentially not volatile at 77°F and has not been reported as an atmospheric contaminant (Cerdeira and Duke, 2006). When glyphosate is applied directly to plant leaves, the risk of drift is low, but when glyphosate is applied broadly to a field, the risk of drift increases (Owen, 1998).

The use of glyphosate as a post-emergence herbicide leads to an increase in no-till farming, which can lead to a decrease in tractor use (Fawcett and Towery, 2002). In fact, emissions related to global warming, ozone depletion, summer smog and carcinogenicity, among others, were found to

be lower in GT crop systems than conventional systems (Bennett et al., 2004). In addition, because the soil is not mechanically disturbed, no-till also results in less dust than tillage, which improves air quality.

3. Water

a. Surface Water

Glyphosate and its metabolite AMPA adsorb to soil particles that become suspended in runoff water and can potentially contaminate surface waters when this soil erodes. Once in surface water, glyphosate and AMPA are not readily broken down by water or sunlight (EPA, 1993), but can be removed through standard water purification processes and disinfection processes such as ozonation and chlorination (Speth, 1994).

In a U.S. Geological Survey (USGS) monitoring study of surface water, groundwater, and soil conducted from 2001 to 2006, the metabolite AMPA was observed more frequently than the parent compound glyphosate (Scribner et al., 2007). The sample collections were from several USGS studies including the National Stream Quality Accounting Network Program, the National Water-Quality Assessment Program, and the Toxic Substances Hydrology Program. Additionally, glyphosate and its metabolite AMPA were found in surface water more frequently than groundwater. Groundwater and surface water contamination by glyphosate is limited because of glyphosate's tendency to adhere to variable-charged soil minerals and because of microbial degradation of glyphosate in soils (Borggaard and Gimsing, 2007). Higher occurrences of glyphosate and AMPA in ground and surface waters were observed when samples were taken near agricultural areas that experienced a rain event shortly after glyphosate application (Scribner et al., 2007). (Please see section 'Glyphosate' above for additional discussion on glyphosate fate in surface water.)

b. Groundwater

Due to glyphosate and AMPA's strong adsorptive characteristics, they are not likely to leach to groundwater from the soil, and compared to most herbicides, leaching is very limited (Cerdeira and Duke, 2006; Grunewald et al., 2001). (Please see section 'Glyphosate' above for additional discussion on glyphosate fate in groundwater.)

IV. Environmental Consequences

This chapter evaluates the potential effects of the preferred alternative (the proposed action of granting nonregulated status to GT alfalfa lines J101 and J163 without restrictions), and the no action alternative detailed in chapter 2 of this EIS. The effects on plant genetics and gene flow, threatened and endangered species, socioeconomic implications, human health and safety impacts, implications for land use and production practices, soil, climate, air quality, and water are considered in this chapter.

A. Methodologies and Assumptions Used in Analysis

1. Models, Risk Assessment, Cause and Effect

The risk characterization used in this chapter to analyze biological impacts of glyphosate use integrates the results of exposure and ecotoxicity assessments to evaluate the likelihood of adverse ecological effects. The means by which this integration occurs is referred to as the quotient method. In this method, risk quotients (RQs) are first calculated by dividing exposure estimates by acute¹⁷ and chronic¹⁸ ecotoxicity values ($RQ = \text{Exposure}/\text{Toxicity}$). RQs are then compared to the EPA's levels of concern (LOCs), which are used by EPA's Office of Pesticide Programs to analyze both potential risk to nontarget organisms and the need to consider regulatory action on pesticides.

Effects of glyphosate exposure to nontarget terrestrial organisms were estimated using the Tier 1 T-REX (Terrestrial Residue Exposure) simulation model (version 1.2.3) based on the maximum application rate, re-application interval, and the default foliar dissipation half-life of 35 days at a rate of 1.99 lb a.i./acre (pound of active ingredient per acre), applied four times at 30 day intervals. Residues on various terrestrial food items ranged from 60.53 to 968.42 mg/kg diet (EPA, 2005). This spreadsheet-based model calculates the residues on avian and mammalian food items along with the dissipation rate of a chemical applied to foliar surfaces (for single or multiple applications) in order to estimate acute and reproductive risk quotients (EPA, 2005).

Glyphosate exposure to aquatic species was estimated using GENEEC (Generic Estimated Exposure Concentration) Version 2.0 (EPA, 2001b) as the Tier I simulation model. GENEEC estimates the peak value which occurs on the day of a single large rainstorm event as well as multiple day averages over periods of 4, 21, 60 and 90 days. The magnitude of the peak concentration is the result of how fast the chemical dissipates in the

¹⁷ Acute toxicity studies are those that study the effects of a single or short-term exposure to a substance.

¹⁸ Chronic studies are those that study the effects of exposure on a large percentage of a subject's life span, such as daily exposure received by workers.

field. The multiple day average over periods of 4 to 90 days reflect the dissipation of the chemical that takes place in the water body. These peak and average concentrations are then compared with the appropriate toxicity tests for aquatic plants and animals. The estimated environmental concentrations for aquatic organisms were based on the application rates proposed in the labels for uses on glyphosate-tolerant (GT) alfalfa. It was assumed that glyphosate was applied in four sequential applications; at least 7 days apart to an annual total maximum of 7.98 lbs glyphosate acid equivalent (a.e.) per acre and that each single application is assumed to be 1.99 lbs glyphosate equivalents per acre. The maximum single use application of 1.99 lbs glyphosate a.e./acre was based on Honcho and Honcho Plus products containing 41 percent of the isopropylamine salt of glyphosate, equivalent to 3 lbs of glyphosate equivalents per gallon (356 g glyphosate/L). This application rate and a minimum reapplication period of 7 days was used to estimate high-end use of glyphosate on GT alfalfa in efforts to quantify the risk to ecological organisms. The maximum single application rate of glyphosate on GT alfalfa is 1.55 pounds a.e./acre, thus, this analysis is highly conservative.

APHIS has no authority under the Plant Protection Act to regulate herbicide use associated with GT plants that are granted nonregulated status. The use of glyphosate is regulated by the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) restrictions administered by the EPA, which mandate registration and use of all pesticides. EPA includes instructions and restrictions on how glyphosate herbicides can be applied, and has determined that there is no unreasonable environmental risk if the user adheres to the directions. Directions include application restrictions that minimize impacts on nearby environments. Violators of the regulations are liable for all negative consequences of their actions; therefore, farmers who use glyphosate are very likely to follow its label restrictions, and adverse impacts from the predicted increased glyphosate use will be minimized. The information is provided to help inform the agency decision maker and the public of the risks associated with glyphosate use. Glyphosate is currently undergoing the reregistration process with EPA.

2. Assumptions a. Data Gaps and Uncertainties

The CEQ regulations recognize that many Federal agencies confront limited information and substantial uncertainty when analyzing potential environmental impacts of their actions under NEPA (40 CFR §1502.22). Accordingly, the regulations provide agencies with a means of formally acknowledging incomplete or unavailable information in NEPA documents.

If the information relevant to reasonably foreseeable significant adverse impacts cannot be obtained because the overall costs of obtaining it are exorbitant or the means to obtain it are not known, the agency shall include within the environmental impact statement:

(1) A statement that such information is incomplete or unavailable; (2) a statement of the relevance of the incomplete or unavailable information to evaluating reasonably foreseeable significant adverse impacts on the human environment; (3) a summary of existing credible scientific evidence which is relevant to evaluating the reasonably foreseeable significant adverse impacts on the human environment, and (4) the agency's evaluation of such impacts based upon theoretical approaches or research methods generally accepted in the scientific community. For the purposes of this section, "reasonably foreseeable" includes impacts which have catastrophic consequences, even if their probability of occurrence is low, provided that the analysis of the impacts is supported by credible scientific evidence, is not based on pure conjecture, and is within the rule of reason. (40 CFR §1502.22.b).

Some of the data on the effects of the deregulation of GT alfalfa are incomplete. Where a complete evaluation of reasonably foreseeable environmental impacts on the human environment that could result from the proposed action and alternatives are precluded by a lack of data that cannot be obtained except at an exorbitant cost or by unknown means, APHIS has complied with the regulations mandated by the CEQ. In these cases, APHIS acknowledges incomplete and unavailable information where the agency is unable to precisely estimate the potential environmental impacts that may result from the preferred alternative.

B. Plant Genetics and Gene Flow

1. Gene Flow Due to Pollen Transfer and Pollination

Preferred Alternative

The discussion throughout chapter 4.B is formed in the context of the preferred alternative. The discussions under each sub-topic are not broken down into both a preferred alternative and a no action alternative discussion, but instead, the no action alternative impacts discussion comes at the end of this section. Unless explicitly defined, all of the following considerations are in relation to the preferred alternative.

Gene flow is a measure of the exchange of genes between populations, and it occurs naturally between alfalfa populations. Review of information previously provided by Monsanto and FGI, information in the Petition 04-110-01p, as well as in the technical report, *The Potential for Gene Flow from Glyphosate-Tolerant Alfalfa (Medicago sativa L.) to Related Species* (appendix I) concludes that alfalfa does not naturally

hybridize with any wild relatives in North America. Having established that there are no related, sexually compatible wild relatives in the United States, movement of the *CP4 EPSPS* gene can only occur to cultivated or feral alfalfa populations through pollination by bees.

Agricultural farmers manipulate bee colonies to control pollination of their crops. For alfalfa seed production, cultured alfalfa leafcutter bees, *Megachile rotundata* (F.), are used primarily in the cooler Pacific Northwest and honey bees (*Apis mellifera* L.) are used primarily in the irrigated valleys of the Desert Southwest (California, Arizona, etc.). In certain niche geographies where suitable climate and soil beds exist (e.g., southern Washington), permanent colonies of the ground-nesting alkali bee, *Nomia melanderi* Cockerell, contribute significantly to commercial alfalfa pollination, and are estimated to contribute 20 percent pollination for alfalfa seed fields proximal to an alkali bee bed. However, alkali bee pollination is often augmented by adding cultured leafcutter bees. Occasionally, some seed producers use a blend of two managed cultured bee species for pollination to increase the rate of seed set or shorten the pollination period.

Hammon et al. (2007) studied alfalfa fields in Colorado and collected data on the insects observed visiting the alfalfa. That list is in table 4-1, in order of abundance, followed by estimated ranges collected from various sources.

Alfalfa farmers purposely stock bees only in seed farming, as they do not want or need pollination of hay fields. Because most regions that cultivate alfalfa seed do not have naturally occurring populations of effective alfalfa pollinators, farmers must produce, introduce and manage these pollinators to ensure pollination (Rogan and Fitzpatrick, 2004). Alfalfa leafcutter bees, a typical managed species for alfalfa seed production, are established next to the target crop of alfalfa. The release of these bees can be controlled by directing incubation temperatures, which signal the bee developmental processes. Alfalfa seed farmers judge when blooming of the crop will be at a peak, and will time the incubation and subsequent release of the bees accordingly. Once the released bees have completed their season and die, the larvae laid throughout the season are collected and cleaned, then stored at a temperature that keeps them in a pupating stage until the desired release time next year. Honey bee colonies, which are not typically used for alfalfa seed production as leafcutter and alkali bees are more effective pollinators (Mueller, 2008), may be moved from field to field because the hives are highly portable and because the bees stay with their queen. Honey bees also tend to forage at much larger distances, and this increases the chances of pollen being spread from one location to another (Strickler and Freitas, 1999; Bosch and Kemp, 2005).

Table 4-1. Pollinator Foraging Distance.

Pollinator (Species)	Forage Distance from Nest
Alfalfa leafcutter bee (<i>Megachile rotundata</i>)	300-600 feet ¹
Honey bee (<i>Apis mellifera</i>)	Measured up to 6.21 miles away, average distance depends on availability of pollen/nectar, typically 1.86 miles ²
Alkali bee (<i>Nomia melanderi</i>)	Will forage up to 4 or 5 miles away; typical pollination within 2 mile radius ³
Long-horned bee (<i>Melissodes</i> sp.)	Data not found
Mud/Digger bee (<i>Anthophora</i> spp.) (2)	Data not found
Bumblebee (<i>Bombus morrisoni</i>)	Data not found
Bumblebee (<i>Bombus griseocollis</i>)	Data not found
Sweat bee (<i>Lasioglossum sisymbrii</i>)	Data not found
Sweat bee (<i>Halictus tripartitus</i>)	Data not found
Sweat bee (<i>Halictus confusus</i>)	Data not found
Leafcutter bee (<i>Megachile texana</i>)	Data not found
Mason bee (<i>Osmia laticulcata</i>)	Data not found

¹ Source: McCaslin et al. (2000)

² Source: Beekman and Ratnieks (2000)

³ Source: USGS, 2008

Bee habits vary based on range and climate. In general, bees will forage where they need to in order to collect pollen and nectar. If there is an abundant source of both close to the nest, then their average foraging distances will be lower than if the bees must forage further to find adequate pollen and nectar. Both honey bees and alfalfa leafcutter bees will increase their foraging distance as the distance to high-reward resources (high nectar and pollen amounts) increases, and as closer resources become scarce (Strickler and Vinson, 2000). Patchiness of the environment also affects this foraging distance, as bees can prefer certain flowers over others (depending on the species and season), and might need to travel through or around obstacles in the environment, so they will adapt foraging habits accordingly (Greenleaf et al., 2007).

It is highly unlikely that physical contact between bees in the hive would result in passive transfer of pollen, which could hypothetically lead, rarely if at all, to a subsequent pollination event and gene flow (Mueller, 2005). According to Johansen (1980 Personal Communication as cited by V. Marble), "...bees clean themselves quite thoroughly back at the hive or nest, concluding that little pollen remained to contaminate a new area of [bee] forage when the bees do not return to the same area of a field on the subsequent trip." This suggests that there is near zero potential for gene flow that might result from passive pollen transfer among cohabitating bees and very little accumulation of viable pollen on the surface of bees that make repeated foraging trips to an alfalfa field or feral grouping of plants. There would be essentially no potential of within-nest transfer of

pollen between bees for most of the native bee species because they are solitary nesting bees.

- 2. Gene Flow Due to Secondary Seedlings** Secondary seedlings (seedlings that are not planted directly by the farmer but rather sprout unintentionally) are an unlikely avenue for effective gene flow into existing solid-seeded alfalfa plantings since alfalfa plants and alfalfa debris produce compounds that elicit an autotoxic reaction to germinating alfalfa seeds. The autotoxic reaction and inter-plant competition severely limit germination and seedling vigor of alfalfa sown or dropped into existing or newly terminated alfalfa stands. Cultivated fields do not successfully self-seed. Attempts to thicken existing alfalfa stands by deliberately inter-planting new seed into them typically fail, which is why most agronomists do not recommend the practice (Canevari et al., 2000).

A portion of seed growers plant their fields in rows instead of solid plantings. In these situations, in-crop volunteers from dropped seeds occur and the resulting seedlings could be a means of gene flow to subsequent crops. However, in order to maintain required variety and purity of the alfalfa crop, these seed growers routinely control germinating alfalfa seedlings and weeds using irrigation and/or soil-active herbicides that do not impact the pre-established, alfalfa crop. The high likelihood of autotoxicity is one reason why alfalfa growers must rotate to a different crop for at least 1 full year following stand take-out.

- 3. Seed Purity** Seed farmers are concerned with the purity of their seed stock, and follow state and federal-mandated standards in order to produce seed of certified purity. Isolation distances between fields and threshold amounts of other varieties that are allowable in a crop vary by state, but in general, seed stock must be 99 percent of the variety or varieties stated on the label. Alfalfa seed production occurs mainly in the West and Northwest United States. California produces the most alfalfa seed in the country, in both pounds and acreage. This is discussed in chapter 3 and in the technical report, *Glyphosate-Tolerant Alfalfa Presence Human Food and Animal Feed* (appendix Q).

In California, in order to cultivate *foundation* alfalfa seed (seed of the highest purity) alfalfa must not have grown on the land in the previous 4 years, and for *certified* seed (seed of the second highest purity), 1 to 2 years, depending on the intervening crops (http://ccia.ucdavis.edu/seed_cert/alfalfa_seedcert_standards.htm). All volunteer plants and noxious weeds must be eradicated and definite boundaries to the field set before field use. Foundation seed fields must be isolated from alfalfa of different varieties by 900 feet, while certified fields must be isolated by 165 feet. However, the 10 percent rule is followed for certified fields, where if 10 percent or less of the certified

field is in the 165 foot isolation zone, the entire field is considered certified, but if more than 10 percent is in the isolation zone, then that part of the field must be separated and not harvested as certified seed. Most states have identical guidelines, with only slight variations, and purity standards remain high. As shown in table 4-2, which shows seed purity standards for California, Idaho, Wisconsin, and Montana, at least 99 percent of each seed harvest must contain the pure seed variety, and there are strict limits on the allowable amounts of other crops, weeds and inert matter as well.

Table 4-2. Seed Purity Standards by State.^{1,2,3,4}

State	Type of Seed	Pure Seed (min %)	Other Crops (max %)	Other Varieties (max %)	Other Material (max %)	Isolation Distance, < 5 acres (ft)
California	Foundation	99.5	0.1	0.1	0.5	900
	Certified	99.5	0.1	0.2	0.5	165
Idaho	Foundation	99	0.1	0.0	1.1	900
	Registered	99	0.1	0.0	1.2	450
	Certified	99	0.25	1.0	1.25	330*
Wisconsin	Foundation	99	0.2	0.1	0.85	900
	Certified	99	0.75	0.25	0.95	165
Montana	Foundation	99.5	0.1	0.1	0.6	1320
	Registered	99.5	0.1	0.25	0.7	660
	Certified	99.5	0.1	1.0	0.8	330

⁴ http://ccia.ucdavis.edu/seed_cert/alfalfa_seedcert_standards.htm

After seed crops have been evaluated by seed labs, they are tagged with seed labels in accordance with law. Seed labs perform multiple tests mandated by the AOSCA (Association of Official Seed Certifying Agencies) on a representative sample from each submitted crop.

Assuming that the contaminating variety has the same germination (the process of a seed beginning to sprout) and fitness (a measure of survival and reproduction) as the certified variety, one can calculate the number of plants in an acre that would be off-type.¹⁹ A thriving alfalfa hay field can have 15 plants per square foot (Orloff et al., 1997), which equals 653,400 plants in an acre (0.5 percent of 653,400 is 3,267). If the contaminating variety is mixed evenly in the seed batch, then there might be an off-type plant every 13.3 square feet. In older stands where plant density may be closer to five plants per square foot, there might be an off-type plant every 40 square feet. FGI's 2000 to 2002 field studies (Fitzpatrick et al., 2002), which assayed 30,000 non-GT alfalfa seedlings, detected 0.000 percent gene flow with a 99.9 percent confidence interval.

¹⁹ Only 60% of the seeds germinate and emerge and only 40% of emerged seedlings survive the first year (Orloff et al., 1997).

This means there could be a 0.01 percent cross-fertilization between non-GT alfalfa and a GT variety, which is one seed in 10,000, or one plant in 667 square feet at a stand density of 15 plants per square foot.

Because of alfalfa seed purity concerns, FGI has expanded the required isolation distances typically used in States that follow the AOSCA standards when growing GT and non-GT alfalfa for seed production. FGI changed the isolation distances for contractors growing alfalfa seed based on scientific studies examining the travel distance of different alfalfa pollinators. FGI's Best Practices, described in more detail below and are a part of the mandatory stewardship program for licensed GT alfalfa seed growers (alfalfa hay growers follow the mandatory stewardship program as described by the Monsanto Technology/Stewardship Agreement), states that when farmers contract with FGI to grow and produce alfalfa seed and use leafcutter bees for pollination, the distance between GT and non-GT alfalfa seed production fields must be greater than or equal to 900 feet. When using Alkali bees, the isolation distance must be greater than or equal to 1 mile, and when honey bees are used as a pollinator, the isolation distance must be greater than or equal to 3 miles. FGI has validated their Best Practices for seed production and believes they can produce non-GT alfalfa seed reliably with >99.5 percent purity (FGI, 2007). To put this in context, one seed in 200 could be from an off-variety, such as GT alfalfa seed in conventional alfalfa seed.

4. Gene Flow to Other Alfalfa Crops and Wild Relatives

Gene flow (the movement of genes from one population to another) occurs naturally among alfalfa in hay fields, seed fields, feral and other alfalfa populations via bees and secondary seedlings. Potential environmental impacts due to gene flow from GT alfalfa to cultivated or feral (free living) alfalfa are considered by APHIS to be no different from cultivation of conventional alfalfa and the resulting potential for gene flow from conventional alfalfa. In the event that GT alfalfa plants were no longer regulated under 7 CFR part 340, we do not believe that the natural flow of genes and traits between alfalfa populations in the United States amounts to a significant impact on the human environment for the following reasons:

- No *Medicago* species are native to the Western Hemisphere; hence, there will be no impact on the natural genetic resources of these species from release in the United States (Sinskaya, 1961; Lesins and Lesins, 1979; Ivanov, 1988).
- If GT individuals did arise through intraspecific hybridization (between two sub-species of the same species), tolerance to glyphosate would not confer any competitive advantage to these plants unless exposed to glyphosate. This would only occur in managed ecosystems where glyphosate is applied for broad-spectrum weed control or in

plant varieties developed to exhibit glyphosate tolerance and in which glyphosate is used to control weeds.

- As with GT alfalfa volunteers, these individuals, should they arise and where they require control, could be controlled using other available chemical and/or mechanical means. Undesired crosses, if they developed, would not be controlled by the use of glyphosate and control would require use of non-glyphosate vegetation management practices. Currently, glyphosate is not widely used to control unwanted alfalfa vegetation (Rogan and Fitzpatrick, 2004).

The following section discusses the factors that influence gene flow between alfalfa fields and potentially increase or decrease the chances of gene transfer between alfalfa plants.

As previously discussed (see chapter 3), there is no evidence for existence of any sexually compatible, free-living or cultivated relatives of *Medicago sativa* in the United States or North America. Thus, possible movement of the transgene via pollen from GT alfalfa events J101 and J163 to other members of the *Medicago* genus would not occur in the United States, or it would only occur following the introduction and establishment of a reproductively compatible, non-native species near GT alfalfa events J101 and J163. It is reasonable to predict that hybridization between rangeland *falcata* subspecies and GT alfalfa varieties with mostly *sativa* parentage would result in hybrids with more rangeland hardiness than the original GT alfalfa, but less rangeland hardiness than the *falcata* parent.

The three alfalfa populations discussed in this section are defined as follows (based partly on Bagavathiannan and Van Acker, 2008):

- *Hay field population*: agricultural field that is intentionally planted with alfalfa and is harvested for hay (may also include some grazing).
- *Seed field population*: agricultural field that is intentionally planted with alfalfa and is harvested as seed stock.
- *Feral and other alfalfa*:
 - *feral*—alfalfa growing on any non-agricultural land (including roadsides, fences, waste lots) that reproduces without intentional human inputs, including reseeding. This is considered the “naturalized” population in the United States because alfalfa was introduced to the continent at least 200 years ago (Putnam et al., 2001).
 - *habitat/rehabilitation/erosion control*—alfalfa that is intentionally sown (most likely in a seed mix), but is not managed after planting.
 - *rangeland*—seed may be sporadically sown for grazing, but land is not mowed for regular hay harvest, populations are mostly self sustaining.

- *volunteer*—alfalfa growing unintentionally, out of rotation in an agricultural field with another crop (e.g., corn).
- *escaped volunteer*—alfalfa from seed that escaped from an agricultural field (this is the first generation of a feral population). Escaped volunteers may not persist past a generation or two, depending on conditions.

There are several factors that influence the probability of gene flow between these fields. The following is a list of factors adapted from Putnam (2006):

- probability of synchronous flowering (e.g., the percentage of days where several plants flower simultaneously);
- availability of pollen (e.g., the percentage of bloom during each day of synchronous flowering);
- pollinator activity on days of synchronous flowering and placement of bee hives (e.g., influenced by timed bee release and weather);
- distance between fields (alfalfa populations);
- probability of seed maturation; and
- probability of seed germination.

Considering the various factors mentioned above, table 4-3 below presents the relative potential of gene flow between hay fields, seed fields and feral and other alfalfa, under the possible nine scenarios of gene flow. This topic is also discussed in the technical report, *Glyphosate-Tolerant Alfalfa Presence in Human Food and Animal Feed* (appendix Q).

Gene flow between and into alfalfa seed fields is of higher concern than gene flow into alfalfa hay fields, whether maintaining the purity of a GT variety or a non-GT variety. This is primarily because hay fields are typically harvested before 10 percent of plants reach full flower (before they can be pollinated), so even if pollen from a GT alfalfa arrives at a non-GT hay field, propagation of seed is highly unlikely.

Even in instances where weather or equipment failures delay harvesting of GT or non-GT alfalfa hay fields, there is little risk of GT gene flow into alfalfa production if it is not wanted (Van Deynze et al., 2008). Alfalfa must bloom, be cross-pollinated by insects, set fruit, and then dehisce seed in order to successfully transfer genes from one plant to another. Alfalfa requires at least four weeks of appropriate environmental conditions (temperature, sunlight, nutrients, and water) before forming reproductively mature floral buds, and an additional 4 to 6 weeks after that to form mature seeds after pollination (Rogan and Fitzpatrick, 2004). Alfalfa hay normally is harvested at or before first flower, 6 to 9 weeks before the ripe seed stage (Putnam, 2006).

Table 4-3. Relative Potential for Gene Flow Between Populations of Alfalfa (requires that viable seed is produced).

<i>Pollen Donor</i>	<i>Pollen Acceptor</i>		
	Seed field	Hay field	Feral and other alfalfa
Seed field	Between adjacent fields with synchronous flowering, gene flow would be expected to exceed 1% which is not acceptable for foundation or certified seed. The largest data set collected under actual seed production conditions using FGI Best Practices found a range of gene flow from 0.00 to 0.18 percent. Thus, FGI Best Practices that include distance between fields can manage cross-fertilization to below 0.5 percent which is FGI's goal.	Lowest risk of gene flow because hay is cut before seed is produced.	Feral populations should be controlled near seed fields to preserve seed purity. However, if feral plants are present, they will likely be cross-pollinated by seed field pollen.
Hay field	Less likely than seed to seed gene flow. The percent bloom at harvest will influence how much pollen could potentially be transported to seed fields. Mowing hay prior to 10 percent bloom and distance (350 to 600 feet) from seed fields can manage cross-fertilization to below 0.01 percent.	Lowest risk of gene flow out of the nine scenarios. Even in fields that bloom, hay is cut before seed is produced.	The percent bloom at harvest will influence how much pollen could potentially be transported to feral populations. Mowing hay prior to 10 percent bloom can reduce pollen availability. Seed farmers will need to be aware of seeding practices in neighboring rangelands because falcata (yellow-flowered alfalfa) may become increasingly adopted for rangeland forage improvement and the Falcata seed is available commercially ¹ .
Feral and other alfalfa	Feral populations need to be controlled near seed fields, or purity of GT and non-GT varieties can be compromised. (Or the seed field edges can be harvested as a separate crop.) Seed farmers will need to be aware of seeding practices in neighboring rangelands because falcata (yellow-flowered alfalfa) may become increasingly adopted for rangeland forage improvement and the Falcata seed is available commercially.	Lowest risk of gene flow because hay is cut before seed is produced.	Gene flow between feral individuals that are close to each other is likely. Gene flow between feral populations depends on proximity, pollinators, flowering timing, and environmental stresses. The GT trait is not expected to impart increased fitness in feral alfalfa.

Source: Van Deynze et al. (2008)

¹ <http://www.windriverseed.com/15212%20-%20Falcata.pdf>

Thus, there are realistic measures that non-GE alfalfa farmers can employ that will effectively reduce or prevent gene flow from neighboring GE alfalfa crops. As stated by Van Deynze et al. (2008):

“Growers who wish to avoid gene flow (e.g., those who produce hay for markets that reject GE crops) should pay attention to flowering habits (avoiding simultaneous flowering) and harvest schedules, and disallow or remove commercial beekeepers’ hives. Although the hay harvest date can be delayed a week or more by wet weather or equipment failure, harvesting before the ripe seed stage is possible in all but the most extreme circumstances.”

In those extreme weather circumstances, rainfall or snow during the ripening time will cause decreased seed yield and reduces seed quality (e.g., reductions in seedling vigor and reduced percent germination because of fungal pathogen infection of the seed, or seed will sprout prematurely and die while it is still in the pod) (Rincker et al., 1988), further reducing the likelihood of gene flow. Additionally, viable alfalfa seeds that fall near adult alfalfa have a harder time growing because they must compete for nutrients with the already established adults, and adult alfalfa plants secrete an autotoxic substance into the soil that inhibits root growth in seedlings (Xuan et al., 2005). In fact, reseeding fields to fill gaps from dead plants is not recommended, as the new plants do not compete efficiently enough to survive (Orloff et al., 1997).

Feral alfalfa is a concern if it is not managed near seed fields. Feral alfalfa near GT alfalfa hay fields may receive the GT trait, but the trait’s survival in the feral population depends on whether there is pressure from the environment to select for plants that maintain the trait, or chance. The GT trait is not expected to enhance feral alfalfa fitness; there is no difference between GT and non-GT alfalfa in terms of alfalfa’s ability to reproduce or persist in an environment (USDA-APHIS, 2009).

Rangeland alfalfa (*falcata* subspecies) populations may be growing as ranchers intentionally seed *falcata* into rangeland to increase forage quality and soil nitrogen (Waggener, 2007; High Plains Midwest Ag Journal, 2008). The potential for gene flow between GT alfalfa and *falcata*, as well as the effect of hybridization between GT alfalfa and the *falcata* subspecies is unstudied.

Factors Decreasing Probability of Gene Flow

FGI and Monsanto have developed mandatory stewardship programs to address concerns regarding gene flow (FGI, 2007).²⁰ Seed growers

²⁰ The stewardship programs also address other concerns such as weediness potential and glyphosate-resistant weed formation.

undergo training and have to be licensed to grow GT alfalfa seed. Any farmer who purchases GT alfalfa seed for producing hay is required to sign a Monsanto Technology/Stewardship Agreement (MTA). The FGI (Forage Genetics International) Best Practices for alfalfa seed growers is the primary mechanism for limiting gene flow. Features of the MTA and FGI Best Practices are as follows (FGI, 2007):

- GT alfalfa seed producers may not sell seed to any party other than FGI and growers may not save seed for any purpose.
- Bee hives cannot be moved out of GT alfalfa fields until pollination is finished for the year. This prevents pollen being carried via hive between GT and non-GT alfalfa. Grower must indicate main pollinator species on the FGI Seed Grower Contract.
- Isolation through distance from other alfalfa fields is required. For pollination with leafcutter bees the distance must be greater than or equal to 900 feet, for Alkali bees greater than or equal to 1 mile, for honey bees greater than or equal to 3 miles.
- FGI reports seed field location and planting date to local seed certifying organizations, which GE-sensitive farmers can refer to in order to certify isolation distances.
- Stand removal and volunteer management must be sufficient to allow seed certification inspectors to validate stand removal. Stand removal date and method must be reported to FGI and verified.
- Cleaning requirements for equipment are included in the FGI Best Practices.
- The Monsanto MTA requires alfalfa hay growers to harvest at or before 10 percent bloom.

Additional factors that could further decrease the potential for gene flow include:

- *Barriers between fields*—Types of barriers can include bodies of water, or other, more attractive plants for bee foraging in between fields. A border of plants at field edges has the benefit of being a buffer zone, as pollen would be deposited in the border population before leaving a GT alfalfa field. If the border were also alfalfa, this would ensure that pollinators would not preferentially avoid the border area. However, the border would need to be treated as GT alfalfa, and if it starts out as non-GT alfalfa, then the spread of genes from that population to the GT alfalfa could adversely affect the cultivation of GT alfalfa seeds by reducing seed purity. If the border were not alfalfa, but a different plant, this would prevent bees from traveling far from the field, and fewer GT genes would be spread. However, this could be difficult if the border plant has different growing and management requirements from the alfalfa, or if it is an attractive plant to pollinators, which would discourage the alfalfa pollinators from

pollinating the alfalfa, and could encourage distant bees to forage there, increasing long-distance pollen flow. Seeds produced by a non-alfalfa plant could also contaminate the purity of the alfalfa seed crop (Amand et al., 2000; Rogan and Fitzpatrick, 2004).

- *Competition for resources*—Volunteer alfalfa plants must establish themselves and compete for nutrients against adult plants.

Given proper adherence to FGI Best Practices and Monsanto's MTA, the risk of cross-fertilization is well below FGI's goal of less than 0.5 percent (unintended or unplanned presence of GT alfalfa).

Factors Increasing Probability of Gene Flow

Certain factors have the potential to increase gene flow between alfalfa crops, as has been discussed in the technical report, *Glyphosate-Tolerant Alfalfa Presence in Human Food and Animal Feed* (appendix Q). If GT alfalfa is deregulated, there would be no restrictions or permits required to grow GT alfalfa. Factors that may increase gene flow between alfalfa populations include, but are not limited to the following:

- *Feral alfalfa creates gene flow corridors*—If feral alfalfa grows between fields of GT alfalfa and non-GT alfalfa, then it could provide a corridor for gene flow, or a strip of growth that can serve as a reservoir for the GT gene, between these fields. It could act as a stepping stone for pollinators that would be more likely to travel between flowers that are closer together than between distant fields.
- *Pest management strategy*—Some farmers use a pest management strategy which allows for a strip of uncut alfalfa during hay harvest. This alfalfa strip can act as a reserve for insect predators. If these alfalfa strips are not harvested at the same time as the rest of the field, they would have the chance to flower, receive pollinators, and set seed. If the strip was GT alfalfa, this would result in a low risk of pollinators mediating the distribution of the GT trait, potentially including feral populations if they occur nearby (Mueller, 2005).
- *Seed field proximity can increase gene flow between the fields*—The seed fields are generally found in a compact geographic area, and with pollinators that have the potential to forage over miles (honey bees, for instance), this creates the potential for cross-pollination in non-GT alfalfa seed fields (Hubbard, 2008).
- *Presence of volunteer alfalfa*—As with any agricultural crop, there is the possibility of volunteer alfalfa growing in the field during other crop rotations. If these volunteer plants were GT, normal glyphosate-based herbicide routines would not eradicate them, creating a possibility that the volunteer plants would flower, set seed, and be a source of pollen for gene flow (Altieri, 2000). Also, alfalfa produces “hard seeds”, which have hard coatings that prevent moisture from

germinating the seed. It is possible that these seeds can remain dormant through growing seasons and germinate at a later time, creating the possibility of adventitious presence even after alfalfa is no longer produced in a field (Hubbard, 2008).

- Movement of honey bees from crop to crop could increase the chance of transferring pollen from one field to another.
- If farmers release too many bees to pollinate one alfalfa seed field, this can lead to unintended and wide dispersal of the bees. This is because bees respond to the competition at one field, and if there are too many in one field, they will forage to find nectar and pollen or to establish nests at alternate sites where there is less competition. This might happen before they visit any flowers of the target field, or they might visit the target field before traveling, increasing the potential of gene flow from the target field (which may be GT alfalfa) to other fields (possibly non-GT alfalfa) (Bosch and Kemp, 2005).

If alfalfa farmers take these factors into consideration and employ measures to counter these factors, such measures should also help alfalfa farmers effectively reduce or prevent gene flow between neighboring alfalfa crops. Combined with the measures discussed above that can be employed to decrease the probability of gene flow between alfalfa fields and crops, we do not believe that the potential for flow of genes and traits between alfalfa populations in the United States should amount to a significant impact on the human environment.

5. Weediness and Increased Glyphosate Resistance

Weed management is an important aspect of alfalfa production. Some of the negative effects of weeds include the following (Canevari et al., 2007; Canevari et al., 2006; Van Deynze et al., 2004; Loux et al., 2007; Miller et al., 2006; Orloff et al., 1997):

- competition with weeds can reduce yield and cause thinning in the stand;
- weeds can lower the nutritional quality of alfalfa hay because many weeds are lower in protein (50 percent less protein than alfalfa) and higher in fiber compared to alfalfa;
- poisonous weeds containing toxic alkaloids (a type of chemical) can make alfalfa hay unmarketable (e.g., common groundsel, fiddleneck, yellow starthistle, and poison hemlock);
- under some conditions weeds can accumulate toxic nitrate concentrations (e.g., lambsquarters, kochia, and pigweed);
- some weeds with a spiny texture can cause mouth and throat ulcerations in livestock (e.g., foxtail, wild barley, cheatgrass, and bristlegrass);
- weeds that are unpalatable to livestock result in less feeding and, therefore, less productivity (of either beef or milk);

- some weeds can contribute to off flavors in milk (e.g., wild celery, Mexican tea, creeping swinegrass, and mustards); and
- weeds that contain higher moisture content than alfalfa (e.g., dandelion) can cause bale problems such as mold, off-color hay, and high bale temperatures, which are a fire hazard.

Without weeds, alfalfa can grow at a density of about 12 plants per square foot. Heavily weed-infested stands can have less than one alfalfa plant per square foot (Canevari et al., 2007). In California, if weeds are not effectively controlled, they can represent up to 76 percent of the first cutting yields (Gianessi et al., 2002).

Farmers are very interested in effective weed control, and GT alfalfa allows the use of glyphosate to eradicate weeds without damaging the crop. However, although relying on glyphosate alone as the only weed removal herbicide may influence the number of weed species that may become glyphosate-resistant (weeds that inherit the ability to survive and reproduce following glyphosate applications that are normally lethal) (Puricelli and Tuesca, 2005; Stoltenberg and Jeschke, n.d.), it is not the only factor involved in the evolution of glyphosate resistance in weeds.

A number of genetic, biological/ecological, and operational factors are involved in determining if a weed species will evolve a resistance to any herbicide (Georghiou and Taylor, 1986; Neve, 2008). Genetic factors include the frequency of genes in a weed species that promotes resistance to a particular herbicide, the ability and rate of changes to genes to cause resistance, the way genes for resistance are passed down to offspring, and the fitness of the plant (and these genes) in the presence and absence of a herbicide. Biological and ecological factors include how the weed species reproduces (selfing or outcrossing), seed production capacity, seed bank turnover, and amount of gene flow within and between populations (Maxwell and Mortimer, 1994; Jasieniuk et al., 1996; Neve, 2008). The genetic factors and biological/ecological factors involved highlight that different species may present different risks of resistance, depending of the genetics of the weed and the biology of the plant. Operational factors involved in the evolution of weed resistance include the type of chemistry and how the herbicide kills plants, frequency the herbicide is applied, and dose and pattern of herbicide application. For many of the genetic, biological/ecological, and operational factors that influence the evolution of herbicide resistance in weeds, accurate measurements are difficult, or impossible, to obtain experimentally (Jasieniuk et al., 1996).

Modeling has been used, but because of the difficulty in obtaining accurate information on the factors indicated above, the use is limited (Jasieniuk et al., 1996). Neve (2008) has used simulation modeling to examine the evolution of glyphosate resistance in weeds. Of the many

assumptions in the model, an important one is that the model only accounts for the evolution of glyphosate resistance in weeds in an annual crop, like herbicide-tolerant corn, where the weeds are only removed when the crop is harvested at the end of the growing season. Alfalfa, on the other hand, is a perennial crop, and when produced as forage, is regularly harvested by mowing during the growing season. Harvesting forage alfalfa has the added benefit of also mowing weeds, which may not have had time to produce flowers, pollen or even seed. Thus, although the genetic factors of a weed species growing in a corn and alfalfa field would likely be the same, the biological and ecological factors may be quite different because of potential reduction in reproductive capability, seed bank formation, and the amount of gene flow within and between the weed species in the alfalfa field compared to the corn field. Neve (2008) modeled the influence of seed bank turnover and seed production characteristics in a continuous glyphosate resistant crop rotation over a 10-year period. At year 10 in the simulation, lower seed bank turnover and low seed production capacity, which may be comparable to the environment in a GT alfalfa forage system, can drastically reduce or even eliminate the probability of weeds becoming glyphosate resistant.

Operational factors also play an essential role in determining the risk of glyphosate use resulting in the evolution of glyphosate-resistant weeds. Neve (2008) found that in year 3 of the simulation, in an annual, glyphosate resistant crop that used five applications of glyphosate at different points during the growing season (before crop seeding, at crop seeding, at pre-emergence of weed, and two post-weed emergence applications), there was a 100 percent probability that a weed species would evolve resistance to glyphosate. In contrast, for GT alfalfa forage production, glyphosate is applied, at most, 4 times a year. In fact, the comments submitted in January and February 2008 to the Notice of Intent for this EIS indicate that no more than two applications of glyphosate are used on GT alfalfa for forage. Furthermore, the application rate for GT alfalfa (1.55 pounds of glyphosate a.e. per acre) is reduced by half compared to the full field application (3.85 pounds of glyphosate a.e. per acre) in other GT crops. Thus, the operational factors for GT alfalfa forage production may decrease the probability of weeds evolving resistance to glyphosate.

Currently, there is no concrete data, information, or models that provide a prescriptive determination on if or how many weed species may evolve resistance to glyphosate, or how many years it may take for a single weed species to evolve resistance, or which management strategy will completely prevent the evolution of weed resistance to glyphosate, or which management strategy will result in all weed species evolving resistance to glyphosate. APHIS is not aware of any models that simulate

the evolution of weeds resistant to glyphosate in a GT alfalfa production system.

There is potential for an overall decrease in total herbicide use due to increases in glyphosate use (see *Glyphosate and Herbicide Use and Comparative Toxicity*, below, and *Potential Impacts to Wildlife, Amphibians, Plants, and Ecosystems from Increased Glyphosate and Other Chemical Usage*, appendix N). However, if there is an increase in glyphosate-resistant weeds due to the adoption of GT alfalfa, there could be a corresponding increase in the amount of other herbicides used for stand removal for non-GT alfalfa.

Weediness Potential of Alfalfa

Under the preferred alternative, GT alfalfa with the inserted CP4 EPSPS gene can be introduced in cropping systems just like cultivated alfalfa. APHIS has previously reviewed information submitted to the agency by Monsanto and FGI on the weediness characteristics of GT alfalfa and have determined that the transformation process and insertion of the CP4 EPSPS gene in GT alfalfa events J101 and J163 have not altered the weediness potential of alfalfa (USDA-APHIS, 2009). Although volunteer crops can become problem weeds in some settings, Rogan and Fitzpatrick (2004) conclude that GT alfalfa will not be any more of a problem weed in a non-agricultural setting than non-GT alfalfa.

Information submitted relating to the use of glyphosate for control of feral alfalfa indicates that feral alfalfa is rarely controlled with herbicide and if controlled, glyphosate is not the herbicide of choice for control. Thus, the GT trait does not provide a competitive advantage to feral alfalfa, and other herbicides are available to control alfalfa that may be tolerant to glyphosate (Rogan and Fitzpatrick, 2004).

Less than 100 percent alfalfa stand termination can result in volunteer alfalfa plants in the following crop. Therefore, good stand termination procedures would still be a good method of eliminating volunteer GT alfalfa plants. Non-glyphosate herbicides and tillage are recommended for effective GT alfalfa stand removal (Orloff et al., 1997).

Monsanto's guidance for GT alfalfa stand removal is summarized in the technical report, *Effects of Glyphosate-Resistant Weeds in Agricultural Systems* (text box 3.1 in appendix G). Based on the available information on this subject, alfalfa is not an important weed in the United States, but care should be taken with other GT crops that may be chosen to follow GT alfalfa in a crop rotation.

Use of GT Alfalfa for Weed Management

The following discussion of GT alfalfa and weed management was based largely on the technical report, *Effects of Glyphosate-Resistant Weeds in Agricultural Systems* (appendix G).

GT alfalfa can be used by farmers for weed management in alfalfa crops. Its unique characteristics allow for effective weed control throughout the growing season of an alfalfa crop, and compared to other GT crops that are commercially available, alfalfa and alfalfa farming practices have characteristics that will aid in the suppression of the development of glyphosate-resistant weeds. Alfalfa's perennial nature, autotoxicity, and nitrogen fixing ability are different from other GT crops, and reduce the likelihood of glyphosate-resistant weed development. Crop rotations with plants that can follow alfalfa, such as annuals (plants that sprout and die each year, and do not regrow from the same seed the next year) or plants that need high amounts of nitrogen in the soil and regular mowing to remove weedy plant mass also help to minimize glyphosate-resistant weeds. These factors are explained below.

Alfalfa produced for forage purposes (e.g., hay and silage in either GE, conventional or organic production systems) is mowed regularly at a recommended cutting height of 3 inches. This removes all plant material higher than 3 inches, including weeds (Orloff et al., 1997), which may not have had time to produce flowers, pollen or even seed. This regular removal of all plant mass above 3 inches of the soil surface, including all weed material, greatly suppresses or eliminates seed production in weed species, and is especially effective in controlling annual weeds.

In a GT alfalfa farming system for forage, the combination of broad spectrum weed control from glyphosate (which should lead to more vigorous alfalfa competition), and regular mowing, which reduces the likelihood that any glyphosate-resistant weeds in the GT alfalfa field have had time to produce pollen or set seed, greatly decreases the probability of the development of glyphosate-resistant weeds. In seed production, mowing only occurs once, as one crop is removed each year; thus, there is a potential for greater weed seed production compared to alfalfa forage production. However, in order to maximize yield for a seed crop, alfalfa seed production currently receives significantly higher herbicide inputs to reduce weed cover than in alfalfa forage production. The additional herbicides with other modes of action may also work to reduce weed seed production and minimize glyphosate-resistant weeds in the seedbank of GT alfalfa grown for seed.

The ability for alfalfa to fix nitrogen encourages the decision to follow alfalfa in the rotation with a crop that requires additional nitrogen, such as

the annual grasses of corn and various cereal crops. These subsequently rotated crops can tolerate a spectrum of herbicides substantially different from the herbicides used in alfalfa. This encourages rotation of crops and herbicides, both of which are highly recommended for reducing the probability of developing herbicide resistant weeds.

All other commercially available GT crops are annuals. As discussed above, simulated modeling indicates that the biological/ecological factors and the operational factors for annual GT crops, point to the potential for faster evolution of glyphosate resistance in annual weeds compared to GT alfalfa. Likewise, perennial conventional alfalfa produced for several years in the same location could favor an increase in perennial weeds if the weeds have the ability to survive repeated mowing; however, no experimental data or modeling specific to GT alfalfa is available to substantiate this prediction.

The use of GT alfalfa for weed control and management may not be appropriate in the following situations (Dillehay and Curran, 2006):

- alfalfa-grass mixtures and alfalfa seeded with companion/nursery crops;
- fields that have a history of low weed populations; and
- fields that are rotated between alfalfa and other GT crop varieties (e.g., Roundup Ready® soybeans).

Van Deynze et al. (2004) reported that in field trials when Roundup® (a glyphosate-based herbicide) was applied during alfalfa stand establishment at the 3 to 4 leaf stage, weeds were controlled and usually no second application was needed. Early applications allowed for late germination of weeds while later applications allowed weeds to compete with alfalfa. If glyphosate is sprayed early enough, alfalfa plants containing the GT trait will fill in gaps left by dead weeds and non-GT alfalfa that was killed (Van Deynze et al., 2004).

Nineteen states have records of glyphosate-resistant weeds (Heap et al., 2008), and all of these states produce alfalfa. The likelihood that glyphosate-resistant weeds will appear in a GT alfalfa field increases with both the number of sites of glyphosate-resistant weeds in a state (Heap et al., 2008) and the acreage planted to alfalfa in a state (USDA-NASS, 2009). The greatest potential for overlap between glyphosate-resistant weeds and GT alfalfa fields occurs in the states of Kansas, Ohio, Illinois, and Missouri. These four states have more than 100 sites of glyphosate-resistant weeds, and each state has over 200,000 acres planted to alfalfa. Although California also has more than 200,000 acres of alfalfa, it has a slightly lower likelihood of overlap between glyphosate-resistant weeds and GT alfalfa because there are less than 70 sites with glyphosate-

resistant weeds. Similarly, Indiana, Michigan, Minnesota, Kentucky, Oregon, and Pennsylvania also have greater than 200,000 acres planted to alfalfa, but each State only has 10 or fewer sites of glyphosate-resistant weeds. The remaining States with records of glyphosate-resistant weeds (Arkansas, Delaware, Georgia, Maryland, Mississippi, New Jersey, North Carolina, and Tennessee) have from 10 to over 500 sites of glyphosate-resistant weeds; however, these States do not have large acreages devoted to alfalfa. Rotation between perennial and annual crops along with the application of glyphosate on the GT alfalfa, alfalfa's natural autotoxicity, and the farming practice of mowing (in forage production) or intensive management practices (in seed production) decreases the probability of a single weedy species surviving these major stresses to become a glyphosate-resistant weed.

Weed Shifts in GT Alfalfa and GT Alfalfa Weed Management Options

The limiting factor for weed control in non-GT conventional alfalfa is that by the time alfalfa reaches the stage of growth that is tolerant to herbicides, weeds are also beyond the stage when they are easily killed with herbicides (Gianessi et al., 2002). Adopting new weed control strategies eventually leads to shifts in composition and/or distribution of the weeds that are of greatest concern.

Weed shifts can occur in GT alfalfa due to tillage, irrigation, soil fertility, planting date, crop rotation, and herbicide use (Hilgenfeld et al., 2004). Changing production to a no-till system results in a more diverse seedbank. Within weedy species variations in characteristics such as seed dormancy, emergence patterns, growth plasticity (the variation in the growth of the plant), life cycle, life duration, shade tolerance, late-season competitive ability, seed dispersal mechanisms, and morphological (physical form) and physiological (biological functioning) variations, help weeds escape or tolerate weed management (Hilgenfeld et al., 2004).

Factors that influence weed shifts in GT agricultural production systems include:

- composition of the weed seedbank in the soil,
- glyphosate application, and
- rotation patterns in a site-dependent manner.

The studies described below exemplify how the above factors affect weed community shifts. If the weed seedbank is largely composed of dormant seed, weed shifts may not be apparent for years, depending on the weed species present. If glyphosate-resistant weeds already occur in an area with a GT crop, glyphosate applications will promote the appearance of more glyphosate-resistant weeds in a field, causing a shift toward a

glyphosate-resistant weed community. Crop rotation between GT and non-GT crops and the use of non-glyphosate herbicides can reduce the populations of glyphosate-tolerant weeds, thus alter weed shifts in GT crops.

- *Composition of weed seedbank and surrounding sources of weeds*—Weed seedbanks in the soil can contain large reservoirs of dormant weed seed; thus, short-term studies (a few years) might not detect the full potential shift in weed communities (Harker et al., 2005). However sometimes weeds shift can be observed within a few years. In a field trial in an established GT alfalfa stand in the Southwest (San Joaquin Valley) burning nettle was not controlled and the population of burning nettle increased significantly over the 3-year trial period (Canevari et al., 2004; Van Deynze et al., 2004). Tank mixtures with Velpar (hexazinone) or paraquat controlled burning nettle. Van Deynze et al. (2004) recommend that the best way to prevent weed shifts is to avoid using the same herbicide year after year, rotate herbicides and crops, and include non-herbicide strategies to control weeds. Weeds that are difficult to control with glyphosate, such as dodder and cheeseweed, may need to be treated early and may require a second application. Smother crops should be planted before alfalfa to suppress weeds. For example, sorghum-sudangrass hybrid or foxtail millet both suppressed weeds and enhanced subsequent alfalfa establishment (Forney et al., 1985).
- *Glyphosate application*—Puricelli and Tuesca (2005) found that continuous glyphosate application in field studies on three crop rotation sequences and two tillage systems lead to quantitative and qualitative changes in weed communities. They found that glyphosate application was a more important factor than crop sequence to explain weed community changes in summer crops. They also predicted that continual glyphosate application for longer than the 5 years in their study might lead to the development or higher increases in abundance of weeds resistant to glyphosate. Weed species diversity in conventional versus no-tillage plots did not differ significantly.
- *Rotation patterns in a site-dependent manner*—Harker et al. (2005) reported that field studies of spring wheat-canola-spring wheat rotations of various combinations of GT and non-GT varieties under conventional tillage or low soil disturbance direct seeding systems indicate that weed community shifts are dependent on rotation pattern in a site-dependent manner. In the western Canada field locations, within 3 years, crop systems without GT varieties were associated with green foxtail, redroot pigweed, sowthistle spp., wild buckwheat, and wild oat. The specific weeds associated with all GT variety systems included Canada thistle at the Brandon site, henbit at the Lacombe site, and volunteer wheat, volunteer canola, and round-leaved mallow at the Lethbridge site. There was high variability in wild buckwheat

between the systems. Glyphosate is not very effective on wild buckwheat, so the authors proposed that wild buckwheat seed production or viability may be restricted by glyphosate more than the wild buckwheat biomass. Therefore, after glyphosate application the plant may appear visually robust, but its ability to reproduce has been effected, so in following years less wild buckwheat is observed (Harker et al., 2005).

It is plausible that the 18 weed species that are both resistant to glyphosate and traditionally present problems in alfalfa (see chapter 3) likely pose the greatest threat for weed shifts in a GT alfalfa crop system. These 18 species may be the first candidates for weed shifts in GT alfalfa. However, as discussed in the studies summarized above, weed shifts are dependent on the composition of the weed seedbank in the soil, surrounding sources of weeds, glyphosate application and site specific rotation patterns. All 18 of these weed species are able to grow as naturalized populations in the United States (<http://plants.usda.gov/index.html>). For maps of the current naturalized populations for these species refer to the technical report, *Effects of Glyphosate-Resistant Weeds in Non-Agricultural Ecosystems* (appendix H).

Chapter 3 summarized the current distribution for glyphosate-resistant weeds in crops. In areas where these resistant biotypes are already present in the seedbank there is a greater potential for increase of those weeds if glyphosate is used. For weed species where glyphosate-resistant biotypes have not been identified in the United States (e.g., buckhorn plantain, goosegrass, junglerice, sourgrass, and wild poinsettia) there are presumably no glyphosate-resistant biotype seedbanks in U.S. soil. Resistant biotypes of these weeds could spread to the United States either through inadvertent transportation or local evolution of resistance.

No Action Alternative

Under the no action alternative, gene flow due to pollen transfer and pollination would be no different than the current situation. The approximately 200,000 acres of GT alfalfa already planted would continue to be harvested and there would be no increase in the cultivation of GT alfalfa. New plantings of GT alfalfa would be considered “regulated” environmental releases and would require a permit. There would be no change in the natural occurrence of gene flow between alfalfa populations. Once the current GT alfalfa stands are removed, likely after a 3- to 4-year period, the GT trait is not likely to be imparted to secondary seedlings, seed fields, hay fields and feral or other alfalfa populations because regulated environmental releases have permit conditions to minimize

pollen movement from the site of the environmental release. Seed purity would not be affected under the no action alternative.

Also under the no action alternative, the weediness potential of alfalfa would remain the same because GT alfalfa and non-GT alfalfa are similar in terms of growth and reproduction, independent of whether GT alfalfa is granted nonregulated status. Once the GT alfalfa standards are removed, there would not be higher quality hay with lower weed populations and lower crop injuries. In those acres that currently produce GT alfalfa, genetic, biological/ecological and operational factors suggest that the use of glyphosate in GT alfalfa would not select glyphosate-resistant weeds as strongly as in other GT annual crops. However, experimental data does not exist to empirically document that glyphosate used in GT alfalfa does not result in an increase in glyphosate-resistant weeds in GT alfalfa fields. Genetic, biological/ecological and operational factors also suggest that glyphosate use in the GT alfalfa that is currently grown would alter weed shifts differently than in GT annual crops. However, experimental data does not exist to empirically document glyphosate use in GT alfalfa would alter weed shifts differently than in GT annual crops. In non-GT alfalfa fields, glyphosate would continue to be used as a stand takeout herbicide, but is not likely to change the appearance of glyphosate-resistant weeds or alter weed shifts in non-GT alfalfa fields. However, experimental data does not exist to empirically document that glyphosate use in non-GT alfalfa would not likely to change the appearance of glyphosate-resistant weeds or alter weed shifts in non-GT alfalfa fields. The no action alternative is not likely change the potential appearance of glyphosate-resistant weeds and/or weed shifts in GT alfalfa or non-GT alfalfa.

C. Biological Impacts

APHIS assessed the potential impacts, if any, of Threatened and Endangered species (T&E) exposed to the gene product of GT alfalfa, and/or an increase in glyphosate-based herbicide application expected in GT alfalfa systems (technical report, *Potential Impacts to Wildlife, Amphibians, Plants, and Ecosystems from Increased Glyphosate and Other Chemical Usage* (appendix N)).

Preferred Alternative

- | | |
|---|---|
| 1. Impacts to T&E Species from GT alfalfa J101 and J163 Gene Product | The full deregulation of GT alfalfa is expected to result in an increase in the prevalence of GT alfalfa events J101 and J163 from the current exposure due to 200,000 acres of GT alfalfa already in production, and an associated increase in the likelihood of exposure of threatened and endangered species to their gene product. APHIS analyzed the potential impacts of GT alfalfa events J101 and J163 on T&E species. Direct effects were evaluated to determine whether an impact was expected on |
|---|---|

any listed or proposed T&E species or any designated critical habitat from directly contacting, consuming, or hybridizing with GT alfalfa events J101 and J163 and/or its progeny

(http://ecos.fws.gov/tess_public/pub/listedAnimals.jsp;

http://ecos.fws.gov/tess_public/pub/listedPlants.jsp;

<http://crithab.fws.gov/>; all accessed January 2009).

- GT alfalfa events J101 and J163 are not expected to become more invasive in natural environments or have any different effect on critical habitat (designated by the Endangered Species Act) than their parental non-GT line in the absence of glyphosate selection. This conclusion is based on results of more than 150 field trials conducted over a 5-year period in 33 different states (Rogan and Fitzpatrick, 2004). The data show GT alfalfa events J101 and J163 are essentially equivalent to non-GT variations in form and shape, such as growth habit, vegetative growth, and flower and pollen morphology (USDA-APHIS, 2009). Several agronomic traits were evaluated and no biological differences between GT and non-GT alfalfa were noted for traits that may influence weediness, including seed dormancy, seed germination, seedling emergence, seedling vigor, winter survival, spring vigor, seed yield, vegetative growth, plant dormancy, survival, and relationship with symbiotic organisms (USDA-APHIS, 2009).
- Analysis of forage samples from several locations demonstrates that it is compositionally and nutritionally equivalent to other alfalfa varieties currently on the market except for the expression of the transgene protein, and therefore is not expected to have nutritional effects on any T&E species that feeds upon it (technical reports, *Presence of Glyphosate-Tolerant Alfalfa in Human Food and Animal Feed* (appendix Q), and *Character and Quality of Glyphosate-Tolerant Alfalfa Traits* (appendix U), (FDA, 2004) [appendix P], (Rogan and Fitzpatrick, 2004).
- The transgene protein does not have toxic or pathogenic effects that would affect T&E species or their critical habitat. The EPSPS protein from plants and from the CP4 *Agrobacterium* strain are not known for pathogenic or toxic effects on human, animal, or plants based on numerous laboratory and field studies with these purified proteins or plants expressing these proteins (technical reports, *Presence of Glyphosate-Tolerant Alfalfa in Human Food and Animal Feed* (appendix Q), and *Character and Quality of Glyphosate-Tolerant Alfalfa Traits* (appendix U), (FDA, 2004) [appendix P], (Rogan and Fitzpatrick, 2004). Nor do the proteins dispose plants to become more susceptible to disease (USDA APHIS, 2009). The same CP4 EPSPS enzyme is expressed in numerous glyphosate-tolerant crops already grown on millions of acres across the United States.
- GT alfalfa events J101 and J163 are not expected to form hybrids with any State or federally listed threatened or endangered species of plants

or plant species proposed for federal listing (technical report, *The Potential for Gene Flow from Glyphosate-Tolerant Alfalfa (Medicago sativa L.) to Related Species* (appendix I)).

After reviewing possible effects of granting nonregulated status in whole to GT alfalfa events J101 and J163, APHIS has not identified any stressor that could affect the reproduction, numbers, or distribution of a listed T&E or species proposed for listing. Consequently, an exposure analysis for individual species is not necessary. APHIS has considered the effect of production of GT alfalfa on designated critical habitat or habitat proposed for designation and could identify no difference from impacts that would occur from the production of other alfalfa varieties (non-GT varieties or organic varieties). APHIS has reached a conclusion that the release of GT alfalfa plants J101 and J163 or their progeny, following a determination of nonregulated status, would have no effect on federally listed threatened or endangered species or species proposed for listing, nor is it expected to adversely modify designated critical habitat or habitat proposed for designation, compared to current agricultural practices. Consequently, a written concurrence or formal consultation with the United States Fish and Wildlife Service or the National Marine Fisheries Service is not required.

No Action Alternative

Under the no action alternative, there would be no change in the likely exposure of T&E plants and animals to GT alfalfa events J101 and J163. Exposure due to the approximately 200,000 acres currently planted to GT alfalfa would remain the same. After the GT alfalfa stands were removed (likely after 3 to 4 years), exposure to GT alfalfa would be limited to those permitted GT alfalfa environmental releases. No change in effects, compared to any current effects due to non-GT alfalfa, would be expected on T&E species or critical habitat under the no action alternative.

Preferred Alternative

2. Impacts to T&E Species from Herbicide Application

Under the preferred alternative, GT alfalfa is expected to result in a potential increase in the use of glyphosate-based herbicide formulations and the reduction/elimination of other, more environmentally toxic herbicides. APHIS received 16 comments from GT alfalfa farmers during the public comment period for the Notice of Intent in January and February 2008 that provided quantitative details on their farming practices. These GT alfalfa farmers account for approximately 24,415 acres of the 200,000 acres currently planted to GT alfalfa (12.2 percent), and apply either 1 or 2 applications of glyphosate on their GT alfalfa crop, instead of using glyphosate during stand take-out. If these applications are ground applications, the total pounds of glyphosate (a.e.) applied to these 24,415 acres of GT alfalfa is between 37,843 (1 application) and

75,687 (2 applications) pounds. According to the growers of GT alfalfa, the amount of glyphosate applied to GT alfalfa is concurrent with the elimination of between 2 and 4 applications of other herbicides used during the production of non-GT alfalfa, including Arrow, Firestorm, diuron, Velpar, Raptor, Pursuit, Poast, Treflan (all with greater environmental impact quotients compared to glyphosate (see table 5.2.1 in technical report, *Potential Impacts to Wildlife, Amphibians, Plants, and Ecosystems, from Increased Glyphosate and Other Chemical Usage* (appendix N)).

Under the preferred alternative, instead of experiencing glyphosate exposure only during stand take-out, T&E animal and plant species within and adjacent to GT alfalfa fields could be exposed to glyphosate up to twice a year via aerial drift and surface water runoff. T&E animal and plant species within and adjacent to GT forage alfalfa fields may be protected by the elimination of up to four exposures to other, more environmentally harmful herbicides, as discussed in chapter 3 and the technical report, *Potential Impacts to Wildlife, Amphibians, Plants, and Ecosystems from Increased Glyphosate and Other Chemical Usage* (appendix N).

APHIS has no authority under the Plant Protection Act to regulate herbicide use associated with GT plants that are granted nonregulated status. The use and application rate of glyphosate is regulated by the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) restrictions administered by the EPA, which mandate registration and use of all pesticides. EPA includes instructions and restrictions on how glyphosate herbicides can be applied, and has determined that there is no unreasonable environmental risk if the user adheres to the labeled directions. Directions include application restrictions that minimize impacts on nearby environments. Individuals applying pesticides must do so in a manner not only consistent with federal laws, but also consistent with state laws and regulations which differ from State to State. In general, States have primary authority for compliance monitoring and enforcing against use of pesticides in violation of the labeling requirements. Violators of the regulations are liable for all negative consequences of their actions, therefore, farmers who use glyphosate are very likely to follow its label restrictions, and adverse impacts from the predicted increased glyphosate use can be expected to be minimized. The information in this section is provided to inform the public of the risks associated with glyphosate use. Glyphosate is currently undergoing the reregistration process with EPA.

In 2008, Monsanto Company released a report entitled, “Overview of the Analysis of Possible Risk to Threatened and Endangered Species Associated with Use of Glyphosate-Containing Herbicides in Alfalfa

Production” (Honegger et al., 2008). The report included a risk assessment conducted to analyze the risk of direct effects of glyphosate and Roundup® agricultural herbicides to threatened and endangered animal and plant species. This assessment follows in large measure EPA’s overview document on endangered species effects determinations (EPA, 2004) and EPA’s Environmental Fate and Effects Risk Assessment for the new uses of glyphosate on bentgrass (Termes and Reider, 2006; EPA, 2006), from which the majority of the environmental fate input parameters and toxicity endpoints were taken to determine Risk Quotient (RQ) values. Based on the risk assessment, the report made the following conclusions, which are supported by an independent APHIS review (technical report, *Potential Impacts to Wildlife, Amphibians, Plants and Ecosystems from Increased Glyphosate and Other Chemical Use* [appendix N]):

- Terrestrial and aquatic T&E animals are expected to be at low risk of direct effects from exposure to glyphosate used in agriculture.
- T&E aquatic plants are expected to be at low risk of direct effects from exposure to glyphosate used in agriculture.
- Terrestrial and semi-aquatic T&E plants are expected to be at low risk of direct effects from exposure to glyphosate used in agriculture at ground application rates less than 3.5 lb pounds acid equivalent per acre (a.e./A).
- Terrestrial and semi-aquatic T&E plants may be at risk of direct effects from exposure to glyphosate used in agriculture at ground application rates greater than or equal to 3.5 lb a.e./A and aerial application rates greater than or equal to 0.7 lb a.e./A.

Because T&E plant species may be at risk from certain application rates of glyphosate in alfalfa production, a more detailed evaluation of the locations of T&E plant species relative to areas of alfalfa production was undertaken. Priester et al. (2007, 2008) determined the co-occurrence of T&E plant species and alfalfa production at the county level and assessed the proximity of land areas where alfalfa could be grown (relevant land use) to sub-county locations of T&E plant species that had been identified as “requiring further analysis” in the county-level analysis. The sub-county species location data for the plant species identified in the county-level analysis were obtained from the FIFRA (Federal Insecticide, Fungicide, and Rodenticide Act) Endangered Species Task Force MJD (Multi-Jurisdictional Database) or from state data sources, where necessary. Geographic information system (GIS) tools were used to compare the locations of the relevant land use with the species locations to assess whether the species had overlap with or was within 250 feet of the relevant land use (Priester et al., 2007; Priester et al., 2008).

The analysis determined that there are counties in 31 States where listed plant species may be in proximity to relevant land use—land that has been

used historically, or is suitable for future for alfalfa production. There are 78 plant species that have been observed to be proximate to relevant land use (Honegger et al., 2008).

Under the preferred alternative, there is the possibility that some of these relevant lands will be cultivated with GT alfalfa. If so, individual plants of 78 T&E plant species are at risk for adverse impacts such as the inability to photosynthesize, the inability to complete respiration, the inability to synthesize nucleic acids and amino acids, and plant death if the individuals in these species are exposed to glyphosate, and the rate of application is equal or exceeds 3.5 pounds glyphosate a.e. per acre or aerial application rates are equal to or exceed 0.7 lb a.e./A (rates that are regulated by EPA pursuant to FIFRA). Ground applications of glyphosate on GT alfalfa are lower (1.55 pounds glyphosate a.e. per acre) than the application rate where plant death may occur (3.5 pounds glyphosate a.e. per acre). Thus, negative impacts on T&E plants due to glyphosate use on GT alfalfa are not likely to occur during ground applications, but negative impacts may occur in situation of aerial applications, which may be applied at a rate of 1.55 pounds glyphosate a.e. per acre and have a higher probability of drifting into neighboring fields. However, the risk due to aerial application is relatively low. Only 2 percent of glyphosate is applied aerially to all agricultural crops in the United States (EPA, 2009). Given that aerial application in GT alfalfa is not expected to be any different than other agricultural production systems, approximately 2 percent of glyphosate used in GT alfalfa is expected to be applied aerially. Further modeling analyzed the use of buffer zones between the GT alfalfa field and potential distributions of T&E plant populations and found that 250 foot buffer negates any negative impacts on T&E plant species due to drift of glyphosate from aerial applications. Therefore, the impacts to T&E plants due to glyphosate use on GT alfalfa could be mitigated by following label use restrictions that maintain application rates below critical levels in the counties where listed species would be within 250 feet of GT alfalfa fields. APHIS, however, does not have the regulatory authority to mandate label use restrictions for glyphosate used on GT alfalfa fields.

No Action Alternative

Under the no action alternative, GT alfalfa would continue to be a regulated article and there would not be an increase in the cultivation of GT alfalfa from the approximately 200,000 acres currently planted. The current use of glyphosate on GT alfalfa is not likely to significantly impact T&E animal species. If the current GT alfalfa fields were managed using ground applications of glyphosate, there would likely be no consequential impacts to T&E plant species from the use of glyphosate herbicides associated with GT alfalfa production under the no action alternative. Any

impacts on T&E species associated with the use of glyphosate on conventional alfalfa fields, and the impacts of T&E species associated with the use of any other herbicide used on conventional alfalfa fields would still occur. Moreover, as explained above in reference to the preferred alternative, use of glyphosate on GT alfalfa fields may eliminate up to four exposures to other, more environmentally harmful herbicides, as discussed in chapter 3 and the technical report, *Potential Impacts to Wildlife, Amphibians, Plants, and Ecosystems from Increased Glyphosate and Other Chemical Usage* (appendix N).

3. Glyphosate and Other Herbicide Use and Comparative Toxicity

Several analyses of pesticide use concluded that herbicide use has been reduced due to the adoption of herbicide-tolerant crops (Brimner et al., 2005; Fernandez-Cornejo, 2006; Gianessi and Reigner, 2006; Kleter et al., 2007; Sankula, 2006; Johnson et al., 2008). One analysis of pesticide use concluded that herbicide application has increased due to herbicide-tolerant crops (Benbrook, 2004). Despite disagreement regarding the overall quantity of herbicide application, all the studies agreed that herbicide use has shifted towards glyphosate. Using standardized methods for ranking environmental impact, researchers have concluded that glyphosate is less harmful to the environment than many other herbicides and that the shift of herbicide use away from more toxic herbicides and to the use of glyphosate has resulted in a net lower environmental impact from herbicides (Kleter et al., 2007).

Weeds in conventional alfalfa cannot be managed completely with glyphosate and are instead controlled using a cocktail of other herbicides (based on OMAFRA, 2008; Canevari et al., 2007; Rogan and Fitzpatrick, 2004; Loux et al., 2007). The 20 other herbicides commonly used on alfalfa have varying chemical fates. In general, most were more persistent and were characterized by higher mobility in soils, making them more apt to continually contaminate surrounding water systems. Also, most have been found to exhibit a higher measured environmental impact quotient (EIQ) relative to glyphosate and have a greater general environmental impact (Kovach et al., 2007).

Preferred Alternative

The full deregulation of GT alfalfa would result in a shift in herbicide use towards glyphosate and away from other, more toxic herbicides used to control weeds in non-GT alfalfa systems under this alternative. There is contradictory evidence on the effect GT alfalfa would have on the overall quantity of herbicide application, although, according to certain studies, it is possible that the deregulation of GT alfalfa would lead to a decrease in the overall amount of herbicides applied (see discussion in chapter 3). For examples, as stated above, APHIS received 16 comments from GT alfalfa farmers during the public comment period for the Notice of Intent in

January and February 2008 that provided quantitative details on their farming practices. These GT alfalfa farmers account for approximately 24, 415 acres of the 200,000 acres currently planted to GT alfalfa (12.2 percent), and apply either 1 or 2 applications of glyphosate on their GT alfalfa crop, instead of using glyphosate once every 3 to 8 years during stand take-out. If these applications are ground applications, the total pounds of glyphosate (a.e.) applied to these 24, 415 acres of GT alfalfa is between 37, 843 (1 application) and 75, 687 (2 applications) pounds. According to the growers of GT alfalfa, the amount of glyphosate applied to GT alfalfa is concurrent with the elimination of between two and four applications of other herbicides used during the production of non-GT alfalfa, including Arrow, Firestorm, diuron, Velpar, Raptor, Pursuit, Poast, Treflan (all with greater environmental impact quotients compared to glyphosate (see table 5.2.1 in technical report, *Potential Impacts to Wildlife, Amphibians, Plants, and Ecosystems, from Increased Glyphosate and Other Chemical Usage* (appendix N)).

Based on the analyses that find glyphosate to be generally less harmful to the environment than the herbicides it replaces in GT alfalfa systems, this shift has the potential to result in lower general environmental impacts in areas where GT alfalfa replaces conventional alfalfa fields. Full deregulation of GT alfalfa would increase the use of other herbicides for stand removal of GT alfalfa. In conventional alfalfa fields, glyphosate is often used to remove alfalfa after 3 to 8 years when it has become vulnerable to weeds and thinning. For stand removal, adoption of GT would likely result in a shift from glyphosate to other herbicides due to the inability of glyphosate to remove stands of GT alfalfa.

No Action Alternative

Under the no action alternative, non-GT alfalfa would continue to be cultivated using conventional herbicide regimes, and glyphosate would continue to be used for stand take-out for non-GT alfalfa. There would not be a shift from other toxic herbicides to comparably less-toxic glyphosate to control weeds in alfalfa cultivation. Because of this, there would be more application of the combination of other herbicides, most of which have a higher measured EIQ. General environmental impacts due to herbicide application in alfalfa cultivation would likely be higher under the no action alternative than it would be under the preferred alternative. However, in order for benefits of the preferred alternative to be realized, GT alfalfa fields would have to replace conventional alfalfa fields. If the preferred alternative resulted in an increase in GT alfalfa cultivation without a corresponding decrease in conventional alfalfa cultivation, the no action alternative would not result in an increase in the net amount of harmful herbicides applied to alfalfa and would result in no effect to herbicide use.

4. Impacts on Plants

Most plant species, when exposed to glyphosate, experience high levels of toxicity. Higher plants that use the shikimate pathway to produce aromatic amino acids will experience toxic effects as they metabolize glyphosate (as discussed in the technical report, *Glyphosate-Tolerant Alfalfa Presence in Human Food and Animal Feed* [appendix Q]). These toxic effects could include the inability to photosynthesize, the inability to complete respiration, and the inability to synthesize nucleic acids and amino acids. Although the effects can be slow to progress, all of these toxic effects could result in plant death (USDA-FS, 2003; Giesy et al., 2000).

Preferred Alternative

The deregulation of GT alfalfa is expected to result in an increase in the use and application of glyphosate-based herbicide formulations (see chapter 3.B.2.). This would lead to an increase in the amount of incidental glyphosate exposure to terrestrial and aquatic plants in the vicinity of GT alfalfa fields either by spray drift, or transport in surface water runoff. However, it is also likely to result in a decrease in the amount of other, more toxic herbicides applied to control weeds in alfalfa fields, as they would be replaced by glyphosate. Because of the high toxicity of glyphosate to plants, as is the case for any herbicide used, deregulation of GT alfalfa could potentially result in adverse effect to plant species near GT alfalfa fields, if they are exposed through aerial drift or runoff of surface waters containing glyphosate. If aerial applications are minimized, this risk to non-target terrestrial plants would be reduced. Because glyphosate binds strongly to soil particles, conservation tillage and no tillage practices have the potential to mitigate impacts to aquatic plants through decreasing soil-laden runoff.

No Action Alternative

Under the no action alternative, the rates and volumes of glyphosate applications would remain unchanged in the context of application to alfalfa fields, resulting in a decrease compared to the action alternatives, except for the 200,000 acres currently under GT alfalfa production. In the cases that the no action alternative precluded conventional alfalfa fields from being converted to GT alfalfa, this would result in the continued use of an array of other herbicides which would be applied at greater volumes compared to glyphosate. The herbicides used in conventional alfalfa systems have been shown, in general, to be more environmentally harmful than glyphosate (Kovach et al., 1992). Therefore the no action alternative has the potential to restrict the replacement of these herbicides with a more environmentally benign alternative. However, the impact of this alternative on specific plant species is unknown as the herbicides used in

conventional alfalfa systems have different effects on different plant species. The herbicides currently used in conventional alfalfa production kill particular groups of plants such as annual grasses, perennial grasses, or broadleaf weed species. Glyphosate, on the other hand, is a single broad spectrum herbicide and is toxic to the vast majority of plant species.

Preferred Alternative

5. Impacts on Animals

The deregulation of GT alfalfa is expected to result in a potential increase in the use and application of glyphosate-based herbicide formulations as more GT alfalfa fields are established, conventional alfalfa fields are replaced with GT alfalfa fields, and fewer pounds of more toxic herbicides are applied in alfalfa fields. This would lead to an increase in the amount of glyphosate exposure to animal species within and adjacent to those fields via aerial drift and surface water runoff, as discussed in chapter 3, and a decrease in exposure to other herbicides.

In general, glyphosate has a low toxicity to animals; however, the end use herbicide formulations are more toxic to certain species. Based on the data available on glyphosate usage on GT alfalfa, chemical fate, and toxicity, and after a Tier 1 “high-end use case” scenario screening of hazard quotients, glyphosate application is not expected to pose a risk if GT alfalfa is granted nonregulated status (see the technical report, *Potential Impacts to Wildlife, Amphibians, Plants and Ecosystems from Increased Glyphosate and Other Chemical Use* [appendix N]). Glyphosate itself is slightly toxic to amphibians; however, amphibians exhibited greater sensitivity to Roundup® formulations than to glyphosate tested as an acid or isopropylamine (IPA) salt. This could be due to the surfactant (POEA) used in agricultural formulations, which has been found to be more toxic to amphibians and other aquatic animals than the herbicide itself (Lajmanovich et al., 2003). Some researchers have suggested that, in combination with POEA, Roundup® could cause extremely high rates of mortality to amphibians that could lead to eventual population declines (Relyea, 2005). However, the testing methods of the Relyea (2005) study have been called into question due to the high exposure doses, which exceed application rates of glyphosate (regulated by FIFRA), as well as the fact that this Roundup® product is not approved for use in an aquatic setting. Additionally, the impacts of the preferred alternative on amphibians are unlikely because Roundup® Weed and Grass Killer (the glyphosate formulation hypothesized to affect amphibians) is not approved for use on Roundup® Ready Alfalfa. Amphibians use a wide range of aquatic habitats for their breeding sites and could be exposed to glyphosate in surface water under full deregulation of GT alfalfa. This would most likely occur as a result of heavy rainfall after a recent application and subsequent dissipation into stream sediment (Lajmanovich et al., 2003).

Although this raises the possibility that the full deregulation of GT alfalfa would potentially have adverse impacts on amphibian populations in watersheds where GT alfalfa is cultivated, this conclusion cannot be made with certainty. There are no experimental studies investigating glyphosate application on amphibian populations to examine potential impacts. However, possible adverse impacts to amphibians resulting from the deregulation of GT alfalfa may be offset by the shift away from other herbicides in GT alfalfa systems which are known to have higher environmental impacts in general. Additionally, amphibian habitat in watersheds where GT alfalfa is produced could be improved under the preferred alternative due to the likelihood that GT alfalfa fields would not be tilled, resulting in decreased soil erosion, decreased sedimentation in runoff, and decreased turbidity in ponds, lakes, and rivers fed by surface waters. However, this benefit would only be realized if conservation tillage in GT alfalfa fields replaced fields that were tilled prior to their conversion.

No Action Alternative

Under the no action alternative, approximately 200,000 acres of GT alfalfa would remain in production, and new planting of GT alfalfa would be regulated. There would be no change in the prevalence of the current GT alfalfa fields in production or the associated use of glyphosate herbicides on in GT and non-GT alfalfa systems. Under no action alternative, the impacts to animals, including amphibians, from the exposure to glyphosate due to GT alfalfa or non-GT alfalfa would be the same. Any effects due to glyphosate use in conventional alfalfa settings, as well as other agricultural systems will still occur. No acute or chronic risk to birds, mammals, terrestrial invertebrates, aquatic invertebrates, or fish due to glyphosate use associated with GT alfalfa would be expected under this alternative; any effects due to glyphosate use in conventional alfalfa settings, as well as other agricultural systems, will still occur. It should be noted that in circumstances where GT alfalfa replaces conventional alfalfa, there is a shift away from more environmentally harmful herbicides towards glyphosate in order to control weeds. Glyphosate has a lower EIQ, and is considered more environmentally benign than the herbicides it replaces in alfalfa production (Kovach et al., 2007), so there is the potential for the no action alternative to result in adverse impacts to wildlife compared to the preferred alternative.

D. Socioeconomic Impacts on Domestic Non-GT Alfalfa Markets

Preferred Alternative

The discussion throughout this section is formed in the context of the preferred alternative. The discussions under each heading are not broken down into both a preferred alternative and a no action alternative discussion, but instead, the no action alternative impacts discussion comes at the end of this section. Unless explicitly defined, all of the following considerations can be assumed to be related to the preferred alternative.

1. Conventional Alfalfa Hay Farming

Evidence of farming distinctions between GT alfalfa and conventional alfalfa come mostly from field trials and from those farmers that planted GT alfalfa during the time period in which it was deregulated (between June 2005 and March 2007). During this period over 200,000 acres of GT alfalfa are estimated to have been planted (Putnam, 2007). Much of the latter type of evidence is anecdotal, and based on the observation of one or a few GT alfalfa fields.

Canevari (2007) presents a small (non-random) survey with 24 growers in addition to a few consultants, seed and marketing dealers, and university faculty which investigated the control of weeds with glyphosate in GT alfalfa. Users of GT alfalfa were generally satisfied with weed control in GT alfalfa. According to this paper, GT alfalfa would reduce the costs of herbicides used while improving the quality of alfalfa hay due to lesser weed content. Miller et al. (2006) refer to field trials done at the University of Wyoming and University of Nebraska and suggest the main features of GT alfalfa are its “ease of use, flexibility, and broad spectrum weed control.” Individual farmers that had experimented with GT alfalfa after initial deregulation and that sent comments to APHIS provide additional reports, including that of possible increase in yields (due to lesser stunting caused by use of other herbicides), eliminating the use of other, more toxic herbicides, and a reduction in herbicide costs.

Given the relevance of yield and quality of alfalfa hay for the determination of economic returns to alfalfa farmers, it is particularly important to understand the impact of GT alfalfa deregulation on these two aspects of alfalfa production. Alfalfa hay yield is influenced by a wide range of factors, including seed variety, proper planting and establishment, climate, soil and moisture conditions, and weed and insect control (Dixon et al., 2005). Hundreds of alfalfa varieties have been developed for use in North America, including a large number of GT alfalfa cultivars (cultivated plants selected because of its useful characteristics). These varieties are adapted to the various major alfalfa

production zones, and all contain genes selected for high yield and resistance to diseases, insects, and nematodes (Van Deynze et al., 2004).

There is no conclusive evidence on whether GT alfalfa presents higher or lower yields than non-GT alfalfa. As shown in table 4-4, variety trial results do not indicate any systematic hay yield advantage or disadvantage for GT alfalfa hay cultivars. Dr. Daniel Putnam, a leading alfalfa research agronomist at the University of California-Davis, has been conducting variety trial testing of GT and other alfalfa cultivars throughout California. Putnam (2008) notes that in general, the yield performance of GT alfalfa cultivars (as a group) are no different than what could be expected from similar conventional lines of equal fall dormancy characteristics. Moreover, he notes that there are differences between conventional varieties that are due to fall dormancy, and due to the superiority of individual cultivars within a dormancy group, but the range of variation observed in conventional cultivars is similar to the range of variation observed in GT cultivars (Putnam, 2008).

Table 4-4. Comparative Variety Trial Yield Results.

With respect to quality, conventional alfalfa hay varies in terms of weed content, and so it is difficult to make direct comparisons between GT and conventional alfalfa hay from a weed content standpoint. Putnam (2008) argues that while the relative weed-free nature of GT alfalfa tends to give it an edge in terms of quality over conventional alfalfa, one cannot systematically attribute higher quality to GT alfalfa over conventional alfalfa, since sometimes conventional weed control systems can be quite effective. However, Van Deynze et al. (2004), Dillehay and Curran (2006), and Rankin (undated) all report better weed control in GT alfalfa using the glyphosate weed management system, suggesting there is the potential for higher quality forage from GT alfalfa.

Based on the discussion above, the scenarios below simulate the impact on economic returns to conventional alfalfa hay farmers from adoption of GT alfalfa under various assumptions. The scenarios stem from the same University of Wisconsin Integrated Pest Crop Management Roundup Ready® Alfalfa Calculator used in chapter 3. Assumptions are changed to allow use of GT seeds, glyphosate, and various scenarios of alfalfa hay quality.²¹ No differences in yield are assumed between GT alfalfa and non-GT alfalfa, and no additional differences in management systems are assumed. Results are shown for the seeding year.

Based on the existing literature, the following values (sometimes ranges) are adopted in the scenarios below. This information can also be found in chapter 3.C.1.

- *GT alfalfa seed costs*—Sold at U.S. \$6-7.50/lb during its deregulation period, including its technology fee of \$125 per 50/lb bag east of the Rocky Mountains, and \$150 per 50/lb bag west of the Rocky Mountains (<http://www.purdue.edu/UNS/x/2007a/070323NeesAlfalfa.html>; <http://ipcm.wisc.edu/WCMNews/tabid/53/EntryID/208/Default.aspx>; <http://www.roundupreadyalfalfa.com/home.aspx?page=valuecalculator>)
- *Glyphosate costs*—Prices have ranged from \$56.30 per gallon in 1998 (USDA NASS, 1998) to \$28.90 per gallon in 2007 (USDA–NASS, 2007); 2008 prices of glyphosate (\$40.50 per gallon) seem to have rebounded from a few years of reduced prices (USDA–NAAS, 2008). The number of glyphosate applications used in the scenarios are one or two per year at 22 ounces/acre.
- *Weed content*—No glyphosate resistance is assumed and only glyphosate is used as an herbicide. Improvements in weed content are built into the scenarios as increases in the quality of hay (for example, from good to premium or to supreme) with reflections on prices, according to USDA available alfalfa hay prices for the relevant locality and year.

In all scenarios summarized in table 4-5, there would be an increase in returns over total costs with the use of GT alfalfa already in the seeding year, as long as the cost of the technology fee is distributed throughout the life of the stand, and in two of the four scenarios even if the cost of the technology fee were fully paid for in the seeding year. Profit per acre

²¹ These scenarios should not be interpreted as likely differentials in costs and returns between conventional and non-GT alfalfa in any particular setting, since the differences in management systems between the two varieties are likely to involve other factors not taken into consideration in the scenarios (such as the time spent by farmers with weed control) and the impact of the deregulation of GT alfalfa on the prices paid for alfalfa of various qualities is ignored.

Table 4-5. Cost Scenarios for GT Alfalfa

						\$50	\$68

Source: first 2 data columns: Integrated Pest Crop Management, U. of Wisconsin; other columns elaborated from base numbers.

¹Apps = glyphosate applications; 2 applications in these columns contrasts with the single application of the first two columns

² Data from various Midwestern markets suggest \$100/ton was the price paid for good quality hay within the last year, while premium quality hay would go for 15-35% more, so the quality improvement assumed is quite modest.

³ Conventional

⁴ Original numbers - shown in the first two columns - prorate seed cost over life of stand but leave full technology fee in seeding year. This assumption is maintained in this table, except for in the third column where the technology fee is prorated as well.

⁵ t/a DM = Tons per acre Dry Matter

would be higher for GT alfalfa in years following that of the seeding year. The increased returns are the result of lower herbicide costs, improved hay quality, or both.

a. Supply of Conventional Alfalfa for Forage

The discussion above suggests a possible reduction in average costs necessary to produce alfalfa of a given quality or, in other words, an increase in the quality of alfalfa hay at a given production cost. The overall impact would be a shift downwards in the supply curve of alfalfa hay. This is represented in figure 4-1 below and would imply a decrease in prices and increase in quantity of alfalfa sold, as dairy and meat farmers substitute alfalfa for other feeds. The following discussion comes in part from the technical report, *Economic and Social Impacts to Conventional and Organic Farmers of Deregulation of Glyphosate-Tolerant Alfalfa* (appendix S).

Figure 4-1. Overall impact on supply with introduction of GT alfalfa.

Within the domestic conventional alfalfa market, however, there is demand for higher and lower quality alfalfa. Since GT alfalfa will likely generate alfalfa hay of high quality (low weed content), the above portrayed shift in supply will be stronger in the market segment for high quality alfalfa forage and may actually shift in the opposite direction (upwards) in the low quality alfalfa segment if farmers currently growing low quality alfalfa hay also adopt GT alfalfa.

b. Demand of Conventional Alfalfa for Forage

The reduction in the price of high quality alfalfa hay will likely have an impact on the demand for alfalfa hay of lower quality, as well as on the demand for alfalfa hay of high quality that is only available at higher costs (non-GT alfalfa). To the extent that high quality and low quality (or higher cost) alfalfa hay are substitutes, a reduction in the price of high

quality alfalfa hay would shift the demand for low quality alfalfa hay downwards.

The main possible impact of GT alfalfa deregulation on the domestic demand for conventional alfalfa hay, however, depends on the existence of a GT-sensitive market among domestic consumers of alfalfa hay. If glyphosate tolerance is seen as an undesirable quality in alfalfa hay by some, these consumers will seek to substitute their purchases by: (a) seeking imported non-GT alfalfa hay; (b) seeking some form of GE-free certification; (c) using GE-free hay based on other crops; or (d) shifting to organic alfalfa hay to minimize the intended presence of GT alfalfa.

Deregulation of GT alfalfa will likely have little or no impact on the domestic demand for conventional alfalfa hay. As discussed in chapter 3, there is insufficient evidence on the sensitivity of domestic demand to the presence of GE material, and any existing preference for non-GE foods would possibly not translate to a reduction in demand. Furthermore, other genetically engineered crops (e.g., corn, soybeans, canola) have been deregulated in the United States for a number of years with no substantial drop in demand for conventionally produced dairy products or meat, the main source of demand for alfalfa hay (Fernandez-Cornejo and Caswell, 2006; Putnam, 2005).

c. Conventional Alfalfa Seed Markets

The main possible advantage of GT alfalfa for seed production is in weed control. Canevari (2007) notes that the ability to control post-emergence dodder (a genus of parasitic plants) before seeding and without injury to alfalfa “would be a significant breakthrough.” However, as noted in the cost studies reported in chapter 3, weed control, although fundamental for seed acceptance in the market, is a lesser cost in seed production than other operational costs such as pollination and insect control.

The market for seed will likely follow the tendency of the market for alfalfa hay, since it is a derived demand. As the quantity of alfalfa hay produced and consumed is expected to increase in a scenario of GT alfalfa deregulation, so would the demand for GT alfalfa seeds. The supply of conventional seeds would be partially occupied by GT alfalfa, according to demand. Myer et al. (1998), using panel data from seven states, find that the demand for alfalfa seed is highly inelastic. In other words, an increase in seed prices does not significantly reduce its demand and is absorbed by seed consumers. This is to be expected given the importance of appropriate seed choice for alfalfa hay yields and quality and the relatively low share of total alfalfa hay production costs represented by seeds.

This discussion is taken in part from the technical report, *Economic and Social Impacts to Conventional and Organic Farmers of Deregulation of Glyphosate-Tolerant Alfalfa* (appendix S).

2. Impacts on Domestic Organic Alfalfa Markets

In the Notice of Intent (NOI) published on January 7, 2008, (73 FR 1198-1200), APHIS requested information regarding the economic impacts of GT alfalfa on organic alfalfa production, given that, at the time of NOI publication, GT alfalfa had already been in commercial production for over two years:

“9. What are the potential economic and social impacts of glyphosate-tolerant alfalfa release on organic and conventional alfalfa farmers? What are the potential impacts of the presence of glyphosate-tolerant alfalfa caused by pollen movement or seed admixtures? What are the economic issues associated with using alfalfa seed or hay commingled with glyphosate-tolerant alfalfa? What are the particular economics of growing seed or hay of organic alfalfa, conventional alfalfa, or glyphosate-tolerant alfalfa? What are the potential changes in the economics of growing and marketing organic and conventional alfalfa that may occur with the use of glyphosate-tolerant alfalfa? What are the potential changes in production levels of other crops that may occur with the use of glyphosate-tolerant alfalfa (i.e., will the release of glyphosate-tolerant alfalfa result in more or fewer acres of corn, wheat, other forage crops, etc.)? What are the potential changes in growing practices, management practices, and crop rotational practices in the production of alfalfa hay or seed for planting or sprouting purposes that may occur with the use of glyphosate-tolerant alfalfa? What are the potential changes in the choice of seeds available for organic and conventional alfalfa farmers that may occur with the use of glyphosate-tolerant alfalfa?”

Unfortunately, APHIS did not receive any specific economic data or information related to the economic ramifications for organic producers due to the production of GT alfalfa. APHIS was expecting data to be submitted during the comment period for the NOI that could be used for predicting the coexistence production costs for organic alfalfa and GT alfalfa, including the costs to organic alfalfa growers to avoid gene flow or the costs associated with organic alfalfa rejected from buyers due to unintended presence of excluded methods (pesticides or genetically engineered crops). Although APHIS did not receive any data from organic alfalfa growers confirming that they in fact have some increased costs in order to implement measures to avoid gene flow from the currently planted 200, 000 acres of GT alfalfa; nevertheless, APHIS is assuming that scenarios exist in which some economic impacts may be felt by some organic alfalfa producers, or those producers who grow alfalfa for

GE-sensitive markets (e.g., for export to certain countries), given the current production of GT alfalfa.

The supply of organic alfalfa hay and organic alfalfa seeds would not be directly affected by adoption of GT alfalfa by non-organic producers of alfalfa. Organic alfalfa growers cannot adopt GT alfalfa because genetic engineering is an excluded method, and GE crops may not be certified as organic. USDA organic certification would also not be affected given that organic certification does not require testing for GE content and focuses on the process used to grow the product—the farming operations—rather than on content of the product itself. From the preamble of the final rule for the National Organic Program:

“Certifying agents attest to the ability of organic operations to follow a set of production standards and practices that meet the requirements of the [Organic Foods Protection] Act and the [National Organic Program] regulations. This regulation prohibits the use of excluded methods in organic operations. The presence of a detectable residue of a product of excluded methods alone does not necessarily constitute a violation of this regulation. As long as an organic operation has not used excluded methods and takes reasonable steps to avoid contact with the products of excluded methods [including genetically engineered crops] as detailed in their approved organic system plan, the unintentional presence of the products of excluded methods should not affect the status of an organic product or operation.”

65 *Federal Register* 80556

Two assumptions are required if organic alfalfa producers are to experience negative economic impacts due to the production of GT alfalfa: a) consumers of organic alfalfa demand alfalfa free from any unintended presence of GT traits; and b) current organic practices and GT alfalfa stewardship are insufficient to minimize cross-fertilization. Organic alfalfa farming production costs may increase due to increased avoidance costs and returns may decrease from the loss in alfalfa production due the presence of GT alfalfa (via cross-fertilization or gene flow) under these assumptions because:

- (1) *Avoidance costs*—If organic alfalfa producers want to avoid unintended presence, whether through adopting buffer zones or requiring testing for GT alfalfa traits in alfalfa seeds used for production, there is a cost of avoidance that must be incorporated into production costs.
- (2) *Loss in production*—If organic alfalfa producers cannot avoid unintended presence above those levels found acceptable by the market, any alfalfa seeds or forage previously destined to those

markets that contain unintended presence of GT alfalfa traits will have to be shifted to markets (i.e., non-organic) that may pay a lower price.

The impact on supply is best understood by imagining two separate market segments: a GT sensitive market (a market that will not accept GT alfalfa) and a non-GT sensitive one (a market that will accept GT alfalfa). If there is loss in production destined to the GT-sensitive market or an increase in costs of supplying that market, the supply curve for that market would shift upwards. If non-GT alfalfa that is destined to the non-GT sensitive market contains GT alfalfa (loss in production), or if some farmers are not able to continue supplying the existing market given the increased costs and shift to the non-GT sensitive market (avoidance costs), the supply curve for that market would shift downwards (see figure 4-2 and the technical report, *Economic and Social Impacts to Conventional and Organic Farmers of Deregulation of Glyphosate-Tolerant Alfalfa* (appendix S)).

Figure 4-2. Impact of presence of GT alfalfa.

A numerical estimation of the impact GT alfalfa deregulation would have on the supply of organic alfalfa, under these assumptions, is not possible given the lack of available information. It would require quantifying the amount of GT alfalfa in organic alfalfa, what share of the organic market is sensitive to unintended presence of GT traits, and what the sensitivity of the demand curve to changes in prices (the price-elasticity of demand) is, since this will determine how much the price would change with shifts in the supply curve.

There is not enough information to evaluate the likelihood of the above scenario. As previously mentioned, it relies on two assumptions: (1) that consumers of organic alfalfa demand alfalfa free from any unintended presence of GT traits; and (2) that current organic practices and GT alfalfa

stewardship are insufficient to minimize unintended presence. However, the existing evidence does not support these two assumptions.

On the first assumption, the demand for organic alfalfa is a demand derived from the demand for organic dairy and beef. Organic dairy represented nearly 90 percent of the total sales value of the combined U.S. organic dairy and meat market in 2006 (Organic Trade Association, 2007) and is by far the main client for organic alfalfa hay.

There is no evidence of GT sensitivity of the demand for organic dairy in a scenario of GT alfalfa deregulation, particularly considering that: (a) current organic standards do not allow for intentional use of GE feed, so any presence of GT traits in alfalfa used for feed in organic dairy or meat farms would be unintended; (b) there is no evidence that any GE material in animal feed currently in use is actually transmitted to milk or meat; and (c) consumer preferences for organic over GE foods are influenced in part by philosophical factors that are likely unrelated to unintended cross-fertilization of feed crops with GE material. Additionally, no quantitative information related to the GT sensitivity on the demand for organic dairy products was submitted during the NOI public comment period, so APHIS has no data to establish or confirm such GT sensitivity.

Survey evidence presented in Brookes and Barfoot (2004) showed that the vast majority (92 percent) of U.S. organic farmers had not incurred any direct additional costs or incurred losses due to GE crops having been grown near their organically produced crops. According to the report, four percent had experienced lost organic sales or downgrading of produce as a result of GE organism presence and the remaining four percent of farmers had incurred small additional costs only for testing. Brookes and Barfoot (2004) also noted that an examination of trends in the planting of GE and organic crops suggests that the growth of the crop area used for GE plants has not impeded the development of the organic sector in North America.

However, as observed in Apted and Mazur (2007), the Brookes and Barfoot (2004) study was not able to quantify the impact of measures undertaken by organic producers to avoid GE material coming into contact with organic crops. Nonetheless, there is data to indicate that farmers using organic production systems are being compensated for the unidentified costs associated with meeting any contractual obligations and NOP standards for alfalfa produced through organic systems. Cost premiums for organic hay production vary between 10 and 50 percent (Lehnert, 1998).

As presented in chapter 3, successful marketing of the National Organic Program (NOP) certified foods has already had to contend with the risk of

GE material accidentally spreading from deregulated cultivars of soybeans, corn, and canola to organic crops. Despite the potential for unintended cross-fertilization, however, organic food sales in the United States continue to grow at a rapid rate. As noted earlier, one reason may be that most U.S. consumers do not appear to have strong or adverse opinions regarding health or safety impacts from GE foods deregulated for U.S. production. Another is that philosophical factors largely unrelated to unintended cross-fertilization are important drivers of organic demand (Anderson et al., 2006). While there is the potential that organic food sales would have grown even more rapidly in the absence of this risk, no published studies have been found that document or estimate this effect.

If there is a segment of the *conventional* market that is sensitive to GT alfalfa, there is actually a possibility for an increase in the demand for organic products, given that much of the information that U.S. consumers currently have regarding purposeful GE content in the foods they eat comes from the presence or absence of organic labels (Ganiere et al., 2006). Consumers of conventional alfalfa that are disinclined to consume GE products could presumably shift their demand to organic products.

The second assumption is that current organic practices and/or GT alfalfa stewardship measures are insufficient to minimize cross-fertilization. However, APHIS is not aware of nor has been provided any data to establish or confirm this assumption. Organic certification under the NOP place the responsibility of managing the potential contact of organic products with other substances not approved for use in organic production systems, whether from the non-organic portion of a split operation or from neighboring farms, on the organic producer. The organic system plan, developed individually by a grower, must outline the steps taken to avoid contact or mixing, and it is the organic producers who are ultimately obligated to manage their operations so as to avoid unintentional contact with non-organic material. This was explicitly affirmed in the response to public comment on the establishment of the NOP (65 FR 80556). The NOP writes specifically about buffer zones and defines them as areas located between a certified organic production operation and an adjacent land area that is not maintained under organic management. A buffer zone must be sufficient in size or other features (e.g., windbreaks or a diversion ditch) to prevent the possibility of unintended contact with prohibited substances applied to adjacent land areas.

The NOP has recognized the practicality of protecting organically-produced crops, and the investment farmers put into their production practices, by requiring that organic production plans include methods to protect organically produced crops.

“Organic crops must be protected from contamination by prohibited substances used on adjoining lands (for example, drifting pesticides, fertilizer-laden runoff water, and pollen drift from genetically engineered...)”(NCAT, 2003).

Typically, more than one method is used under organic practices to prevent unwanted material from entering their fields including; isolation of the farm, physical barriers or buffer zones between organic production and non-organic production, as well as formal communications between neighboring farms (NCAT, 2003). Farmers using organic methods are requested to let neighboring farmers know that they are using organic production practices and request that the neighbors also help the organic farmer reduce contamination events (NCAT, 2003; Krueger, 2007). The organic plan used as the basis for organic certification should also include a description of practices used to prevent or reduce the likelihood of unwanted substances, like GE pollen or seed, at each step in the farming operation, such as planting, harvesting, storing and transporting the crop (Riddle, 2004; Krueger, 2007; Kuepper et al., 2007). Organic plans should also include of how the risk of GE pollen or seed co-mingling will be monitored (Kuepper et al., 2007). Practices that help organic farmers minimize the risk of unintended GE presence in their field include: (1) Use seed that is from a known, non-GE stock (lists of organic seed suppliers can be found at www.attra.org); (2) Use temporal buffers such that alfalfa being produced using organic methods is receptive to pollen at a different time of year than when the neighboring alfalfa flowers; (3) Harvest alfalfa at 10 percent bloom to reduce the number of flowers available for pollination (however, harvesting alfalfa prior to formation of seed (approximately 4 weeks after bloom) will also minimize the potential of gene flow into an organic alfalfa forage field; see table 4-3); (4) remove bee hives surrounding alfalfa fields prior to alfalfa blooming period (5) Maintain physical isolation from GT alfalfa (either through distance or natural barrier (e.g., tree rows)); (6) Plant alfalfa at the edge field to act as a trap for GE pollen and harvest these buffer rows separately.

Thus, commonly used production practices for alfalfa, and the practical methods typically used by alfalfa farmers using organic methods to protect their crop and maximize their profits and price premiums granted to alfalfa under organic production, currently provide many effective measures that greatly reduce the likelihood of accidental gene flow between GT and non-GT alfalfa. APHIS assumes that organic farmers are already using, or have the ability to use, these common, reasonable practices to minimize gene flow between GT and non-GT alfalfa, because organic alfalfa growers have not informed APHIS to the contrary, and because USDA organic certification requires measures to minimize unintended presence to GT alfalfa. Recommended organic production practices for alfalfa are also readily available (Guerena and Sullivan, 2003). It is important to note

that organic production systems have been coexisting with GT alfalfa since 2005 and there is currently 200, 000 planted acres of GT alfalfa.

Additionally, the contractual obligations for GT alfalfa growers also include required measures to minimize the gene flow of GT alfalfa. These measures are mandatory for the GT alfalfa seed growers and include isolation distances for alfalfa seed production fields: when leafcutter bees are used for pollination, the distance between GT and non-GT alfalfa seed production fields must be greater than or equal to 900 feet; when using Alkali bees, the isolation distance must be greater than or equal to 1 mile; and when honey bees are used as a pollinator, the isolation distance must be greater than or equal to 3 miles. FGI has validated their Best Practices for seed production and believes they can produce non-GT alfalfa seed reliably with >99.5 percent purity (FGI, 2007).

Thus, APHIS is not aware of any specific evidence to support the assumption that current practices in either organic production systems or GT alfalfa production are insufficient to minimize the unintended presence of GT alfalfa. The assumptions that support the scenario of increased production costs and reduced demands for organic alfalfa farmers have not been established or documented and APHIS is aware of no data that confirms these assumptions.

On the demand side, in addition to the possible segmentation of the organic alfalfa markets in GT sensitive and non-GT sensitive segments, demand for organic alfalfa hay could shift downwards under two possible scenarios—

- (1) If organic dairy and meat farmers consider shifting to conventional farming due to the decreased costs of high quality conventional alfalfa (and presumably increased returns).
- (2) If the decreased costs of high quality conventional alfalfa are transmitted to conventional dairy and meat costs, increasing the price differential between conventional and organic dairy and meat, stimulating organic dairy and meat consumers to purchase conventional products.

There is no evidence that the first scenario would occur. To the extent that organic farmers have chosen organic production out of philosophical values and/or to supply the organic alfalfa market, the economic incentive to switch to conventional farming should not have an impact.

The likelihood of the second scenario is also not clear. A report by the U.S. General Accounting Office (2001) studied the factors influencing farm and retail dairy prices. The report notes that changes in milk production costs do not necessarily reflect in changes in retail prices of

dairy. Farmer milk prices represent roughly 40 percent of retail milk prices and are affected by Federal and State programs establishing minimum prices. The process of transmission of dairy farms costs to prices is not a simple one to determine. In the case of meat, alfalfa is likely a lower share of feed costs in cow-calf production than it is in dairy production since the main source of feed is grazing (Short, 2001). As cattle move on to feedlots (sometime through stocker operators) feed becomes mostly grain based ration. Short (2001) argues that prices paid for cattle tend to be similar across the country, despite differences in cow-calf production costs because cattle are routinely transported. This suggests that any transfer of cost changes to prices down the chain would be unlikely. Under the unlikely scenario that the supply curve was shifted by presence of GT alfalfa as previously shown, and that the demand curve was shifted downwards by loss of competitiveness of organic products when compared to conventional products, the impact on the organic market would be as shown in figure 4-3.

Figure 4-3. Impact of GT alfalfa deregulation on organic alfalfa for forage with GT-sensitive domestic markets.

The result of GT alfalfa deregulation under this scenario would depend on the extent of the GT-sensitive market within the organic market. The larger the GT-sensitive market is, the more likely quantities sold would decrease, although with an unclear effect on prices. The larger the non-GT sensitive market is, the more likely prices would decrease, but with unclear effect on quantities.

Once again, there is not enough information to estimate numerically the impact for organic farmers under this scenario, even though APHIS in its NOI specifically requested information on the economic impacts of GT alfalfa on organic beef and dairy markets (73 FR 1198-1200). In addition to changes in supply and demand, we also requested data (but did not receive any) on the share of the organic market that is GT-sensitive and the magnitude of the decrease in prices expected of conventional alfalfa. An expansion of this discussion can be found in the technical report,

3. Impacts on Dairy and Beef Markets

Based on the above analyses, we have concluded that the deregulation of GT alfalfa would likely have no impact or minor impact on the domestic demand for conventional or organic dairy and beef products. As discussed in chapter 3 and in the technical report, *Downstream Effects to Organic Production and Marketing of Deregulation of Glyphosate-Tolerant Alfalfa* (appendix T), there is insufficient evidence on the sensitivity of domestic demand to the presence of GE products, and any existing preference for non-GE foods would likely not translate to a reduction in demand. Furthermore, other genetically engineered crops (e.g., corn, soybeans, canola) have been deregulated in the United States for a number of years with no substantial drop in demand for conventionally produced dairy products or meat (Fernandez-Cornejo and Caswell, 2006; Putnam, 2005).

On the supply side, alfalfa is likely a considerable share of dairy feed costs. Short (2004) reports hay and straw (presumably mostly alfalfa) represents roughly a third of feed costs. Alfalfa may additionally be used in cubes or pellets. In some regions (Wisconsin, Minnesota), haylage is also a significant share of feed. As adoption of GT alfalfa would likely increase the quality of alfalfa for forage without an increase in costs, this should increase productivity of non-GT sensitive dairy farms and allow for an increase in production without an increase in costs. The impact on dairy farms would be to increase the feasibility of operations. MacDonald et al. (2007) report that currently many small dairy farms are operating with incomes above operational costs but below total costs (they are not covering overhead and capital recovery costs). The impact on reduced costs would, however, impact farms of all sizes, since feed seems to be of similar importance to all farms. If GT alfalfa requires less labor, this may be to the advantage of smaller farms where labor is a greater share of costs. Whether decreased dairy farm production costs and a potential increase in production would translate into reduced prices for dairy is not clear, as previously mentioned, given governmental regulation of farmer milk prices. As stated above, the effect of GT alfalfa deregulation on the supply of organically produced alfalfa would depend on the extent of the GT-sensitive market within the organic market.

In the case of meat, alfalfa is likely a lower share of feed costs in organic or conventional cow-calf production than it is in dairy production since the main source of feed is grazing (Short, 2001). The impact of potentially reduced alfalfa costs on meat production may be important for cow-calf production, particularly in areas where supplementary feeding is more important in winter, such as the North Central region—Iowa, Illinois, Missouri (Short, 2001). If the alfalfa used is often of lower quality (Klonsky et al., 2007) the impact would depend on the extent to which

reduction in prices of high quality alfalfa also decreases the prices of lower quality alfalfa. It is unlikely; however, that GT alfalfa deregulation would have significant impact on organic or conventional meat farming costs or meat prices, given the relatively low share of alfalfa in production costs.

4. Impacts on Trade

The following discussion is taken in part from the technical report, *Impacts to United States Trade of Deregulation of Glyphosate-Tolerant Alfalfa* (appendix R).

There is considerable dissimilarity among countries on regulation pertaining to GE food and feed (Gruère, 2006). While most countries lack any regulations at all, Japan, Saudi Arabia and South Korea, main alfalfa export markets, all have approval processes for GE products and labeling requirements.

Japan has zero tolerance for non-approved GE foods and conducts inspection and testing of cargoes arriving in Japan, inspecting up to 50 percent of all cargoes (Gruère, 2006). A 1-percent threshold for unintended, or unplanned, presence of GE content in feed is allowed as long as the GE product has been approved by the exporting country and the exporting country is considered to have safety assessments equivalent to Japan's (Gruère, 2006). Labeling is mandatory for all GE foods as long as GE material can be detected, the GE ingredient is one of the first three ingredients of a product, and the GE material accounts for more than five percent of the total weight (Gruère, 2006). Labeling requirements are based only on product content and not process (Gruère and Rao, 2007).

Because alfalfa hay is predominantly used as feed, the impacts of deregulation associated with the export market in Japan may be similar to those of soybeans and corn. Japanese regulations do not seem to have had a significant impact on these crops and labeling is not required for products from GE fed animals—at least not for meat—and corn used for feed is typically GE corn (Gruère, 2006).

However, there is evidence in several countries other than the United States that businesses have often chosen to protect themselves against market risks associated with commercializing GE products, in the face of consumer negative perceptions. A USDA (2005) document notes how business associations have sometimes adopted lower required levels of unintended presence for acceptance of products than those required by legislation (United Kingdom). The same document notes that some insurance companies have added exclusions to insurance contracts to protect themselves from potential losses triggered by the presence of GE material. There is some indication that Japanese alfalfa importers are concerned with importing GE alfalfa. Putnam (2005) states that foreign

importers have asked for GE-free alfalfa and that this has led U.S. exporters to require signed contracts from producers asserting the GE-free status of alfalfa sold to them. Similar anecdotal evidence is provided by Woodward (2004) and recognized by the National Alfalfa and Forage Alliance (2008b).

The United States appeared to have already been steadily losing market share in its exports of alfalfa hay and cubes to Japan before the 2005 deregulation of GT alfalfa. In the 10 years in which Japan's total forage imports increased by 18.5 percent, exports of U.S. forage only increased by 7.5 percent. Although Canada's share of this market has remained stable, Australia's share grew 800 percent from 1995 to 2004 (Woodward, 2006).

Sales in the United States of alfalfa for forage to Japan may decrease with GT alfalfa deregulation. There is evidence of precautionary resistance from Japanese importers for GT alfalfa and the United States has already been losing market share to competitors (Australia). Exporters may have to show that any unintended presence of GT traits would fall well below Japan's 1-percent threshold level for unintended presence of GE feed.

South Korea has similar approval processes and labeling requirements as Japan. Labeling in South Korea is mandatory for unprocessed GE food and for unprocessed non-GE food containing more than three percent unintended presence of GE content. In the case of processed foods, labeling is required if the GE ingredient is among the top five and is detectable in the final product. GE animal feed must also be labeled (USDA-FAS, 2008a). Processed food with non-detectable levels of GE material, such as dairy, meat and vegetable oils do not require labeling.

Non-government Organizations (NGOs) in South Korea have increasingly advocated for expansion of labeling requirements to products using GE ingredients, independently of whether these can or cannot be detected in the final product (USDA-FAS, 2008a). USDA-FAS (2008a) notes that labeling of feed does not seem to have an impact in the market because most feed is GE, but that an expansion of food labeling requirements to include use of GE ingredients even when not detectable could turn South Korea into a non-GE market. As in the case of Japan, there is evidence of consumer negative views of GE products (Cho, Undated; USDA-FAS, 2008a). South Korean businesses, however, have been opposing expansion of GE labeling given the potential increase in their costs from buying non-GE products.

For alfalfa seed, the most important export market is Saudi Arabia. Although the country allows imports of labeled GE variety grains and plant/vegetable processed foodstuffs, imports of GE variety seeds have

been banned since 2004 (USDA-FAS, 2007a). Saudi Arabia would currently not purchase GT alfalfa seeds. Whether Saudi Arabia would continue purchasing non-GT alfalfa seeds from the United States would likely depend on the extent to which non-GT alfalfa seed producers are able to avoid unintended presence of GT alfalfa traits.

Mexico, the main downstream export market for dairy, seems to have no significant trade barriers to foods derived from biotechnology. GT alfalfa has been approved for food and feed in Mexico, and Mexico regularly imports and consumes GE corn, soybeans and cotton from the United States (USDA-FAS, 2008b). Mexico's existing labeling requirements for GE products have not been implemented, according to Gruère (2006). In the case of Canada, another important market for alfalfa downstream products from the United States, GT alfalfa has also been approved and there is no mandatory labeling for GE products (Gruère, 2006).

On the import side, U.S. imports of alfalfa hay and seed come mostly from Canada. To the extent that GT alfalfa deregulation would reduce foreign demand for U.S. exports, alfalfa hay and seed production previously destined to foreign markets would possibly be channeled to the domestic market. As the domestic market for non-GT alfalfa hay and seed would be expected to decrease with GT alfalfa deregulation, U.S. production would possibly substitute imports.

5. Social Impacts

GT alfalfa adoption by farmers, cross-fertilization of non-GT alfalfa fields, and the demand response to GT alfalfa deregulation could have several social impacts, which are further discussed in the technical report, *Economic and Social Impacts to Conventional and Organic Farmers of Deregulation of Glyphosate-Tolerant Alfalfa* (appendix S).

Businesses Lost and Gained

Farmers adopting GT alfalfa would possibly face decreased costs or improved markets for the possibly less expensive GT alfalfa while GT-sensitive farmers would possibly face a reduction in demand for the more expensive organic alfalfa. Early GT alfalfa adopters may gain markets while conventional non-GT alfalfa farmers producing high quality alfalfa may lose, due to potentially higher costs and lower quality when compared to GT alfalfa. If there is GT-sensitivity in the market for organic alfalfa, those organic farmers that are most affected by the unintended presence of GT alfalfa may lose markets, while organic farmers less affected may gain.

Market Structure

Increased land costs that could affect non-GT alfalfa farmers attempting to avoid the presence of GT alfalfa could benefit larger alfalfa farmers. Land costs generating economies of scale in alfalfa grown for forage are also a major cost factor in alfalfa seed production.

The impact of increased land costs on seed production would likely be mitigated, however, by the highly inelastic demand for seeds. In other words, as seed quality is important for alfalfa forage producers and seed costs are a small cost of their total production costs, increases in seeds costs should not significantly affect sales of seeds. Moreover, land costs for GT-sensitive alfalfa forage growers may be reduced as there are other mechanisms available to minimize the presence of GT alfalfa in GT-sensitive alfalfa fields.

If adoption rates of GT alfalfa were high, alfalfa seed farmers would face increased demand for GT alfalfa seeds and would shift production to this variety. There would likely be an increased market concentration in the supply of alfalfa seed technology.

To the extent that organic farming is more suitable for small farms than conventional farming (less economies of scale related to greater dependency of labor), a reduction in the demand for organic products could favor larger farmers. Therefore, overall, alfalfa production may shift to larger farms.

Distribution of Costs of Loss of Production and Avoidance

Based on the assumption that there is a level of presence of GT alfalfa that the organic market will not bear, and to the assumption that current alfalfa production practices are not already in place to protect against unintended presence of GT alfalfa in GT-sensitive alfalfa fields, organic producers could bear a cost in either loss of production or measures to reduce the likelihood of unintended presence. However, APHIS is not aware of nor has been provided with any reliable evidence that currently establishes or supports either of these assumptions.

Social Aspects of Organic Farming

The absence of a GT-sensitive domestic demand for organic products does not mean GE products are necessarily welcome by organic consumers, but rather that any sensitivity to GE content may not translate into a decrease in sales of organic alfalfa. Organic producers (and consumers) would possibly still be unhappy with the outcome. To the extent that organic farming involves broader life choices related to philosophical attitudes,

this discontent would be a negative impact. This situation may conceal a market for GE free products in need of development.

No Action Alternative Socioeconomic Impacts

Under the no action alternative, the opportunity for improved quality and/or reduced costs of alfalfa hay would be lost, except for the 200,000 acres of GT alfalfa currently in production. This would mostly have a negative financial impact on alfalfa hay and dairy farmers. Marketing and business efforts conducted around the over 200,000 acres of GT alfalfa planted during the time in which GT alfalfa was deregulated would also be lost. Organic farmers would neither be negatively affected by potential (although unlikely) increased production costs or decreased demand, nor would it have the opportunity to gain GT-sensitive conventional consumers. Exporters would possibly continue to lose alfalfa hay markets to competitors.

E. Human Health and Safety Impacts

The use of glyphosate herbicide does not appear to result in adverse effects on development, reproduction, or endocrine systems in humans and other mammals, as discussed further in the technical reports, *Potential Impacts to Wildlife, Amphibians, Plants, and Ecosystems from Increased Glyphosate and Other Chemical Use* (appendix N), and *Health and Safety Risks from Increased Glyphosate and Other Chemical Usage on Humans (Exclusive of Field Workers)* (appendix L). Under present and expected conditions of use, glyphosate herbicide does not pose a health risk to humans.

Current weight-of-evidence from similar GE crops such as GT wheat (Peterson, 2005), GT soybean, GT corn, GT cotton, and GT sugarbeet suggests that the transgenic CP4 EPSPS protein present in GT alfalfa poses negligible risk to humans, livestock, and wildlife. Most studies available in scientific literature support the view that food from GT crops is substantially equivalent to non-transgenic crops.

1. Introduction of Gene Product into Foods

As mentioned in chapter 3, it was concluded that the CP4 EPSPS protein produced by GT alfalfa events J101 and J163 was biochemically and functionally equivalent to CP4 EPSPSs produced by other Roundup Ready® crops, and to the family of EPSPS proteins that naturally occur in crops and microbiologically based processing agents that have a long history of safe consumption by humans and animals (U.S. FDA, 2004). Human food uses of alfalfa are minor, with the majority of alfalfa consumed by humans as freshly sprouted seedlings (sprouts) or as compressed leaf material in dietary supplements or herbal teas. Since alfalfa is not a reported allergenic food and may be a relatively minor

contributor to some respiratory allergic diseases, the risk to human health is minimal (Metcalf et al., 1996). Monsanto, the developer of GT alfalfa, pursuant to its mandatory MTA measures for growing its GT alfalfa lines, does not allow GT alfalfa to be planted for sprouts (Hubbard, 2008); therefore, human exposure to GT alfalfa appears to be minimal.

Preferred Alternative

If GT alfalfa is deregulated, there is an increased possibility that the gene product would be incorporated into foods, beyond the currently incorporation into food due to the 200,000 acres of GT alfalfa currently in production. With the deregulation of GT alfalfa, it will be more widespread in the environment, and that will increase the chance that nearby, non-GT alfalfa crops contain GT alfalfa content. This is only a possibility, however, as Monsanto will still not allow GT alfalfa to be planted for sprouts, and Monsanto and FGI will encourage Best Management Practices. The GT alfalfa lines J101 and J163 have both successfully completed the voluntary consultation process with FDA, which evaluated food and feed safety of GT alfalfa (FDA, 2004; appendix P).

No Action Alternative

2. Impact of Introduction of Gene Product into Animal Feed

Humans are already currently exposed to gene product from GT alfalfa events J101 and J163, as this gene product is found in other crops (e.g., soybean). Approximately 200,000 acres of GT alfalfa are currently being grown. For the areas using GT alfalfa, and for those areas that request permits to plant GT alfalfa for research under the no action alternative, the risks to human health and safety from the gene product introduction into food would not change from current conditions.

After reviewing the Monsanto and FGI submission to FDA and other information, APHIS agrees with the FDA assessment and concludes that no concerns exist for the food and feed safety of GT alfalfa compared to conventional alfalfa. Studies on the persistence of plant-derived recombinant DNA in livestock have indicated that feed ingested DNA fragments do survive in the terminal gastrointestinal (GI) tract and that uptake into the GI tissue does occur. There is no evidence thus far to indicate that the recombinant DNA would be digested and metabolized in a manner any different from the genetic material of conventional feed products. Additionally, no negative effects of the CP4 EPSPS protein or gene consumption on the nutritional characteristics of dairy cattle, livestock, or poultry have been reported (Combs and Hartnell, 2007). Field observations of GT alfalfa events J101 and J163 have revealed no negative effects of the transgene on non-target organisms such as bees and earthworms. No effects have been observed on pollen harvest behavior of

workers bees, or on survival and development of honey bee egg, larvae or pupa post exposure to the CP4 EPSPS protein.

Combs and Hartnell (2007) showed that milk production, milk composition, feed intake and feed efficiency were not different for dairy cows fed GT versus control alfalfa hay ($P>0.05$). The nutritional safety of a similar GT crop - maize line GA21, was evaluated by Sidhu et al. (2000) in a poultry feeding study. Results from this study showed that there were no significant differences in growth, feed efficiency, adjusted feed efficiency, and fat pad weights between chickens fed with GA21 grain or with parental control grain. These studies further confirm the feed safety of glyphosate and the CP4 EPSPS protein.

Preferred Alternative

If GT alfalfa is deregulated, in whole, then there is an increased possibility that the gene product would become present in animal feed. With the deregulation of GT alfalfa, it will be more widespread in the environment, and as discussed in Gene Flow (chapter 4.B) that will increase the chance that GT alfalfa may be present in nearby, non-GT alfalfa. Also, as most alfalfa is grown for forage, and the amount of crops grown using GT technology increases, the amount of feed that contains the gene product will increase. As stated, this will likely have no adverse effects on livestock or humans.

No Action Alternative

For the 200,000 acres of GT alfalfa currently in production, it is likely that the gene product in GT alfalfa would have no adverse effects on livestock or humans. If further plantings of GT alfalfa were to require a permit, risks to human health and safety from the gene product fertilization of livestock feed would not change from current conditions. The gene product in GT alfalfa is already present in animal feed. The potential of unintended presence itself would remain low if GT alfalfa remained regulated.

3. Glyphosate Exposure

The use of currently registered pesticide products containing glyphosate in accordance with the labeling will not pose unreasonable risks or adverse effects to humans or the environment (according to EPA). However, there is a concern that glyphosate use in general could increase with the adoption of GT crops, leading to a potential increase in glyphosate exposure. However, glyphosate is of relatively low oral and dermal (via the skin) acute toxicity. For this reason, glyphosate has been assigned to Toxicity Categories III and IV for these effects (Toxicity Category I indicates the highest degree of acute toxicity, and Category IV the lowest). See the technical report, *Health and Safety Risks from Increased*

Glyphosate and Other Chemical Usage on Humans (Exclusive of Field Workers) (appendix L) for this and further discussion.

Where pesticides may be used on food or feed crops, EPA also sets tolerances (maximum pesticide residue levels) for the amount of the pesticide that can legally remain in or on foods. EPA undertakes this analysis under the authority of the Federal Food, Drug, and Cosmetic Act (FFDCA). Under the FFDCA, EPA must find that such tolerances will be safe, meaning that there is a reasonable certainty that no harm will result from aggregate exposure to the pesticide chemical residue. This finding must be made and the appropriate tolerance established before a pesticide can be registered for use on the particular food or feed crop in question. Several factors must be addressed before a tolerance can be established, including:

- the aggregate, non-occupational exposure from the pesticide (exposure through diet, from using pesticides in and around the home, and from drinking water);
- the cumulative effects from exposure to different pesticides that produce similar effects in the human body;
- whether there is increased susceptibility to infants and children, or other sensitive subpopulations, from exposure to the pesticide; and
- whether the pesticide produces an effect in humans similar to an effect produced by a naturally-occurring estrogen or produces other endocrine-disruption effects.

a. Hazard Identification and Exposure Assessment for Field Workers

To determine if workers are at risk of adverse effects associated with glyphosate, estimated exposures are compared with a health benchmark specific to glyphosate. USDA (2003) used a dermal reference dose (RfD) for acute (i.e., accidental) and chronic (i.e., general) exposure scenarios for glyphosate of 2 mg/kg of body weight per day. This means that individuals with dermal exposure doses equal to or less than 2 mg/kg of body weight per day are not at risk of adverse effects associated with exposure to glyphosate. The risk metric used to determine if individuals are at risk of adverse effects is called the hazard quotient (HQ). The hazard quotient is the ratio of the estimated exposure dose to the chemical-specific health benchmark (e.g., RfD) (See Equation below). If the HQ is estimated to be less than 1, no adverse effects are expected as a result of exposure to the chemical of concern. If the HQ is greater than 1, adverse health effects are possible. However, an HQ exceeding 1 does not indicate that adverse effects are certain to occur.

$$HQ = \frac{Exposure}{RfD}$$

Where:

HQ	=	Hazard quotient (<i>no units</i>)
Exposure	=	Estimated exposure dose (mg/kg body weight per day)
RfD	=	Reference dose (mg/kg body weight per day)

See tables 4-6 and 4-7 for HQs calculated for both chronic (general) and acute exposures, which are based on the amounts of chemicals handled per day, the application rates, the acres treated per day, and the dermal absorption rate, among other factors. These calculations are described in further detail in the technical report, *Health and Safety Risks from Increased Glyphosate and Other Chemical Usage on Humans (Exclusive of Field Workers)* (appendix L) and *Health and Safety Risk for Field Workers* (appendix M). Conservative values were used for all of these calculations, in order to get an idea of the worst-case scenario.

Table 4-6. Chronic Dermal HQs for General Worker Exposure Scenarios.

Scenario	Central Estimate	Lower Estimate	Upper Estimate	RfD (in mg/kg BW per day)
Directed Foliar	0.0131	0.0005	0.0800	2
Broadcast Foliar	0.0224	0.0007	0.1512	
Aerial	0.0147	0.0002	0.0800	

Table 4-7. Acute Dermal HQs for General Worker Exposure Scenarios.

Scenario	Central Estimate	Lower Estimate	Upper Estimate	RfD (in mg/kg BW per day)
Spill on hands	0.007	0.002	0.025	2
Spill on legs	0.017	0.005	0.062	

Preferred Alternative

If GT alfalfa is deregulated in whole, then there is no change in impact on exposure risk to individual workers. As discussed, the evaluation of exposure risk is based on factors that do not change based on the amount

of GT alfalfa grown or the number of workers exposed. Exposure risk remains the same for both general, chronic exposure and accidental, acute exposure risks to workers.

No Action Alternative

Continuation of GT alfalfa as a regulated article will result in very little change to exposure risk assessments for workers and the general public, even for the 200,000 acres of GT alfalfa currently in production. Risk assessments were evaluated based on current conditions and measurements. While these assessment values remain the same, the actual chance of exposure to glyphosate residue would remain low if GT alfalfa remained regulated. Exposure to herbicides presently used in alfalfa production, which includes glyphosate during stand takeout, would not change.

b. Risk Assessment

The general public is not at a high risk of exposure to substantial levels of glyphosate under typical use conditions (EPA, 1993; USDA, 2003). Dermal and inhalation routes of exposure are not considered in this analysis because it is assumed that GT alfalfa will not be grown by members of the general public or in close proximity to non-farm populations. Thus, it is assumed that the general public will not directly come in contact with or inhale herbicides recommended for use on GT alfalfa. It is, however, assumed that members of the general public may be exposed orally to these herbicides via consumption of foods that have been treated by herbicides containing glyphosate. Because consumers are likely to be exposed to residues of glyphosate on many food items, exposure scenarios evaluated acute effects from consumption of fruit and vegetables contaminated with residues of glyphosate by adults, the elderly, and infants under 1 year of age. Please see the technical report, *Health and Safety Risks from Increased Glyphosate and Other Chemical Usage on Humans (Exclusive of Field Workers)* (appendix L) for further details and discussion.

In the 1993 U.S. EPA RED (Reregistration Eligibility Decision) for glyphosate, the EPA conducted a dietary risk assessment and determined that non-nursing infants under 1 year of age are at highest risk of adverse effects associated with glyphosate exposure (EPA, 1993). The EPA completed an additional risk assessment for glyphosate in 2006 to address its specific use on Indian mulberry and dried peas (EPA, 2006). In this later assessment, the EPA also found that infants under 1 year of age are at greatest risk. APHIS conducted its own risk assessment, based on factors such as amount of fruit and vegetable consumption, glyphosate application rate, and residue rates on a crop.

The analysis, which used the same RfD as that for the worker exposure scenarios, showed that central and lower hazard quotient (HQ) estimates were all under 1, suggesting that the majority of the population is not at risk of adverse health effects associated with acute exposure to glyphosate (see technical report, *Health and Safety Risks from Increased Glyphosate and Other Chemical Usage on Humans (Exclusive of Field Worker)* (appendix L)). Based on upper estimates of exposure, however, infants consuming fruit and all age groups consuming vegetables may be at risk of adverse effects associated with acute exposure to glyphosate. The age group at highest risk is infants under 1 year of age, which is consistent with EPA's findings (EPA, 2006; EPA, 1993). The upper estimate HQ for infants with acute exposure to fruit was approximately 3. The upper estimate HQs for all age groups with acute exposure to vegetables ranged from approximately 2 to 6. These results are all over 1, suggesting the potential for adverse health effects associated with glyphosate (see tables 4-8 and 4-9). It should be noted, though, that the upper estimates of risk are based on highly conservative fruit and vegetable intake rates and a high estimate of glyphosate residue concentrations; thus it is anticipated that only a very small number of individuals, if any, will have this magnitude of exposure and, therefore, be at this level of risk.

Table 4-8. Acute HQs by Age Group and Scenario.

Scenario	Age Group	Central Estimate	Lower Estimate	Upper Estimate	RfD (in mg/kg BW per day)
Fruit	Adults	0.01	0.00	0.62	2
Fruit	Elderly	0.02	0.01	0.23	2
Fruit	Infants	0.10	0.09	3.16	2
Vegetable	Adults	0.16	0.09	2.30	2
Vegetable	Elderly	0.18	0.11	2.55	2
Vegetable	Infants	0.31	0.00	6.07	2

Table 4-9. Chronic HQs by Age Group and Scenario.

Scenario	Age Group	Central Estimate	Lower Estimate	Upper Estimate	RfD
Fruit	Adults	0.01	0.00	0.34	2
Fruit	Elderly	0.01	0.00	0.12	2
Fruit	Infants	0.06	0.00	1.73	2
Vegetable	Adults	0.09	0.05	1.26	2
Vegetable	Elderly	0.10	0.06	1.40	2
Vegetable	Infants	0.17	0.00	3.32	2

Preferred Alternative

If GT alfalfa is deregulated, then there is an increased possibility that the general public will have more sources of exposure to glyphosate through residues in and on food crops and other foods. With the deregulation of GT alfalfa, GT alfalfa will likely be grown in many areas of the country.

The addition of another GT crop to agricultural production may lead to a greater chance that a GT crop, including GT alfalfa may be grown near food crops. This could lead to higher hazard quotients with respect for glyphosate for the general public because there would be more chance for glyphosate residue to affect food crops. Nonetheless, such increase risk of exposure to glyphosate residue will not result in increased risks to the general population because the current upper estimates of risk are based on highly conservative fruit and vegetable intake rates with an assumed high estimated amount of glyphosate residue; thus it is anticipated that only a very small number of individuals, if any, will have this magnitude of exposure and therefore be at this level of risk. Moreover, the potential exists for decreases in the applications and subsequent residues of more toxic herbicides if GT alfalfa is deregulated.

No Action Alternative

If GT alfalfa is not deregulated, there will be an increased possibility that the general public will have an increased exposure to glyphosate residue due to the approximately 200,000 acres of GT alfalfa currently grown. There will also be decreases in applications and subsequent residues of more toxic herbicides in the areas surrounding the 200,000 acres of GT alfalfa currently in production. In the remaining alfalfa acreage that is not planted to GT alfalfa, there will be no change in the current exposure risk to glyphosate residues or to the current exposure risk to the other, more toxic herbicides currently used in alfalfa.

c. Risk Characterization

Risk characterization integrates the information from the hazard identification, dose-response, and exposure assessments, using a combination of qualitative information, quantitative information, and information regarding uncertainties. In general, the way in which glyphosate acts on plants to injure or kill them (through its metabolic pathway) will not occur in humans or other animals, and, thus, the way in which glyphosate affects plants is not directly relevant to the human health risk assessment. EPA considers glyphosate to be of low acute and chronic toxicity by the dermal route of exposure. Glyphosate is considered a Category IV dermal toxicant and is expected to cause only slight skin irritation. This is corroborated by the low HQs determined from the worker assessments, where there is the greatest likelihood of dermal exposure. Workers using the methods of application analyzed above to apply herbicides, and workers who accidentally spill herbicides, are not at risk of adverse effects associated with chronic or acute dermal exposure to glyphosate.

The analysis concerning exposure to the general public considers the possibility that any type of fruit or vegetable could contain residues of glyphosate (see technical report, *Health and Safety Risks from Increased Glyphosate and Other Chemical Usage on Humans (Exclusive of Field Worker)*[appendix L)). Central, upper, and lower estimates of consumption rates were used to estimate exposure and risk for adults, infants, and the elderly. It is anticipated that the results of this analysis are highly conservative for several reasons. First, the upper bound exposure and risk estimates are based on fruit and vegetable consumption rates characteristic of the 100th percentile of the population (the maximum consumption rate). In addition, in assuming a spray drift of one for all scenarios, this analysis assumes that fruits and vegetables will have the same residue of glyphosate as the GT alfalfa will. Application rates are specific to herbicides used to treat GT alfalfa forage fields, which is not meant for human consumption, as opposed to rates specific to fruits and vegetables. Acute and chronic scenarios assume that fruits and vegetables growing in nearby fields will have residues of glyphosate at the same level; however this is a highly unlikely scenario, but used for the purpose of an initial risk assessment before determining whether there is a need for refined consumption, use or residue data.

In terms of chronic toxicity from oral exposure, one of the more consistent effects of exposure to glyphosate is loss of body weight. Other general and non-specific signs of toxicity from chronic exposure to glyphosate include changes in liver weight, blood chemistry (may suggests mild liver toxicity), liver pathology, and in pituitary weight (USDA-FS, 2003). Glyphosate is not a carcinogen, however, and has been classified by the EPA as a Group E carcinogen (evidence of non-carcinogenicity for humans) (EPA, 2006; EPA, 1993).

Preferred Alternative

If GT alfalfa is deregulated in whole, then there is expected to be an overall increase in exposure to glyphosate as discussed earlier because more glyphosate will be use in areas where it may not be used, or used as much as it is now. However, as described above, the overall risk to the general population and workers is not expected to be different than under the current labeled uses of glyphosate. The above data, calculated by the EPA and USDA, show an overall low risk to human health and safety from glyphosate and GT alfalfa. These analyses were designed as worst-case scenarios, and assumptions most likely resulted in an extremely protective estimate of exposure and risk. The use of currently registered pesticide products containing glyphosate in accordance with the labeling will not pose unreasonable risks or adverse effects to humans or the environment. The general population and workers are not at risk from the deregulation of GT alfalfa.

No Action Alternative

If GT alfalfa is not deregulated, glyphosate, along with other herbicides will still be used in the production of conventional alfalfa, GT soybean, GT cotton, GT corn, GT sugarbeet, other conventional crops, and will be used for the 200,000 acres of GT alfalfa currently under production. The use of currently registered pesticide products containing glyphosate in accordance with the label will not pose unreasonable risks or adverse effects to humans or the environment. There will be no change in the current exposure risk to glyphosate residues, as well as no change in the current exposure risk to residues from herbicides currently being used in alfalfa production.

4. Consumption of GT Alfalfa Events J101 and J163

The CP4 EPSPS protein produced by GT alfalfa events J101 and J163 was isolated from forage and characterized using analytical methods capable of assessing the chemical and functional characteristics of the protein (FDA, 2004). As a result of the characterization, it was concluded that the CP4 EPSPS protein produced by GT alfalfa events J101 and J163 was biochemically and functionally equivalent to CP4 EPSPSs produced by other Roundup Ready® crops and to the family of EPSPS proteins that naturally occur in crops and microbiologically based processing agents that have a long history of safe consumption by humans and animals. All of these data and information taken together demonstrate a history of safe experience with respect to GT crops which have been consumed in significant amounts, either directly or as processed products, by humans and animals since their initial commercialization in 1996.

Preferred Alternative

If GT alfalfa is deregulated in whole, then there is no change in risk from consumption of GT alfalfa. As discussed, the evaluation of risk from GT alfalfa consumption is based on factors that do not change based on the amount of GT alfalfa grown. The gene product is safe for consumption, regardless of regulation status.

No Action Alternative

As with the full deregulation alternative, the no action alternative would not change current levels of risk from GT alfalfa consumption. The gene product has been found to be safe for consumption, and other GT products, as well as products from the 200,000 acres of GT alfalfa under production, are currently on the market.

5. Impacts from Changes in Production Practices to Human Health and Safety

As GT alfalfa is adopted, it is expected that glyphosate herbicide will replace other forms of weed control currently used in alfalfa. Heimlich et al. (2000) noted that using glyphosate in the context of GT crops has resulted in the replacement of herbicides that are at least three times as toxic and persist almost twice as long as glyphosate. For example, in cotton and soybeans fields, for the most part, several herbicides were replaced by glyphosate (million pounds reduction): bentazon (-4.4), disodium methanearsenate (DSMA; -0.8), fluometuron (-4.5), imazethapyr (-1.0), metribuzin (-1.5), methylarsonic acid sodium salt (MSMA) (-1.7), paraquat (-2.9), pendimethalin (-14.0), sethoxydim (-1.1), and trifluralin (-13.0).

Preferred Alternative

If GT alfalfa is deregulated, in whole, then there is no change from the above expected impacts. GT alfalfa will most likely become widely adopted, and glyphosate use will increase (as has been shown, in general, with other GT crops). This will likely result in an overall decrease in the amount and number of other herbicides used. If glyphosate replaces more toxic herbicides, as has been shown for cotton and soybeans and currently for the 200,000 acres of GT alfalfa under production, then this will result in less danger of human exposure to toxic chemicals.

No Action Alternative

The assumed risks from increased glyphosate use during production of GT alfalfa occurring as a result of deregulation would not be of concern. The approximately 200,000 acres of GT alfalfa will remain in production, and for these areas, glyphosate use will increase, and the use of the other herbicides will decrease. However, in areas that remain free of GT alfalfa, any concerns with respect to the current herbicides used in alfalfa production will remain.

F. Land Use and Production Practices

1. Implications for Cultivation Practices

Based on the adoption of other GT crops, it is expected that GT alfalfa will replace conventional alfalfa production, especially where alfalfa is highly managed (e.g., west and southwestern States). It is not expected to be adopted in areas where alfalfa is minimally managed and where inputs are low. These areas include pastures, hay fields, and road sides with mixed stands of perennial grasses and other perennial forage legumes and in these same areas in which herbicides are generally not used to control weeds. As discussed in chapter 4.C.1 and 4.E.5, it is expected that glyphosate herbicide will replace other forms of weed control currently used in alfalfa with the adoption of GT alfalfa. However, disagreement

exists over whether overall herbicide usage has increased in the past as a result of herbicide-resistant crops (see chapter 3.D.2).

There has been some speculation that weed-free alfalfa stands may result in longer stand life, which may subsequently cause a change in land use. Extended stand life provides positive economic and environmental benefits because a significant amount of the total production costs over the life of the stand are associated with the establishment year. These costs include those associated with seed bed preparation, seed, fertilizer, herbicides and pesticides (Ward, 2007). After the stand is successfully established, costs diminish, and extending a healthy stand will increase profitability. In addition, increased stand life would result in less tillage of agricultural lands and growth of additional alfalfa harvests. Since alfalfa is a plant that provides nitrogen to the soil due to a *Rhizobium*-legume symbiotic relationship resulting in high fixation rates of nitrogen that is usable by the following crop (Vance et al., 1988), growing alfalfa could possibly reduce the need for nitrogen fertilizers obtained through the utilization of fossil fuels. Thus, removal of weeds in the final years of the stand without crop injury provides the opportunity to maintain a healthy and weed-free stand (USDA-APHIS, 2009).

Crop rotation options may be different between conventional and GT farming systems. Many of the non-glyphosate herbicides have follow-up planting restrictions that limit crop rotation choices in conventional farming. Farmers using GT cropping systems are advised to include some years of non-GT crops in rotation, so there may be limitations in the use of other GT crops if GT alfalfa is used in a rotation plan.

Herbicides that can be used to remove GT alfalfa have rotation restrictions. For example, following clopyralid (Curtail® or Stinger®), pea, lentil, potato, and dry bean cannot be planted for 18 months. Picloram (Tordon®) can only be followed by grasses for the year after application. Sunflower, dry bean, and potato should not be planted for several years following picloram (Miller et al., 2006). Dicamba (Banvel®) should not be used prior to soybean and is also limited seasonally in California (Dillehay and Curran, 2006). Because of these restrictions, alfalfa stand removal and rotation schedules should be closely coordinated. Non-glyphosate herbicides are available to manage alfalfa volunteers in wheat, oats, barley, sugar beet, and corn. Therefore, rotations from GT alfalfa to those crops should be similar to rotations with non-GT alfalfa (Rogan and Fitzpatrick, 2004).

No-till GT corn can be planted directly into alfalfa. In a study comparing no-till GT corn planted into cut or uncut alfalfa and various herbicide applications to control the alfalfa, corn yield was 13 percent higher following herbicide applications to uncut alfalfa. Application of

glyphosate and dicamba at planting resulted in the greatest corn yield. Given that alfalfa is also a valuable crop, whether the corn yield gain is worth the loss of an alfalfa harvest should be weighed (Glenn and Meyers, 2006).

Preferred Alternative

If GT alfalfa is deregulated, the impact of GT alfalfa on the overall amount of land devoted to alfalfa cultivation is expected to be minimal. The decision for use of agricultural or other lands for alfalfa production is largely a market-driven decision, and the availability of a new weed control option where other options already exist is not expected to impact land use decisions to any great extent. However, due to the broad range of weeds controlled by glyphosate, farmers may choose to plant GT alfalfa on fields with greater weed pressure, and if the life of a stand of alfalfa can be extended longer, this might impact land-use decisions and crop-rotation practices. In general, overall land devoted to alfalfa cultivation will be impacted largely by the price of alfalfa hay and not by the availability of GT technology. It is likely, as seen with other GT crops, that glyphosate use will increase. In general, however, glyphosate is more environmentally and toxicologically benign than many of the herbicides that it replaces (Brookes and Barfoot, 2006).

No Action Alternative

The no action scenario would result in no change to current cultivation practices or land use decisions.

G. Physical Environment

Preferred Alternative

1. Impacts on Soils

The deregulation of GT alfalfa is not expected to have an adverse effect on soils. Although the use of GT alfalfa will result in an increase in the use of glyphosate herbicide formulations, glyphosate adsorbs strongly to soil and does not generally move vertically below 6 inches through the soil. Also, glyphosate is rapidly degraded by soil microbes in the environment into AMPA, but observed concentrations of AMPA are many times lower than where toxic effects might occur (Gimsing et al., 2004).

Deregulating GT alfalfa could indirectly benefit the environment through the soil conservation practices of conservation tillage and no tillage, which would increase in popularity (Wiebe and Gollehon, 2006) because of the reduced cost of these practices and the effectiveness of glyphosate in controlling weeds alone, without the need for tillage. Conservation tillage and no tillage practices would improve soil quality by increasing the soil

organic matter that helps soil bind nutrients and prevents the loss to runoff, erosion, and leaching (Leep et al., 2003). Conservation tillage and no tillage practices likely to be implemented with GT alfalfa also have the potential benefit of mitigating potential minor effects on soil biological/chemical properties because it leads to enhanced organic carbon and plant residues in surface soils.

Mowing would be employed to prevent alfalfa flowering in GT alfalfa systems, resulting in compaction of the soil. However, conventional alfalfa is also commonly mowed to prevent flowering, and is also mowed as a weed control technique. The preferred alternative would require less mowing for weed control and could result in less frequent mowing of alfalfa fields and less soil compaction.

Because soil is the habitat for a wide variety of microorganisms, impacts on soil often correspond to impacts on microorganisms. Although many microorganisms produce aromatic amino acids through the same pathway that glyphosate inhibits in plants, there is little empirical evidence to support the conclusion that glyphosate application results in a negative impact on soil microbes and in some cases, field studies have shown an increase in microbial activity (USDA-FS, 2003). In the cases where GT alfalfa is cultivated using no-till or conservation till systems, there may be positive impacts on soil microbes (Giesy et al., 2000). It is noted that GT alfalfa does not alter the symbiotic association with the nitrogen-fixing bacterium *Sinorhizobium meliloti* and does not negatively affect the availability of nitrogen in the soil (USDA-FS, 2003).

No Action Alternative

Under the no action alternative, the 200,000 acres of GT alfalfa currently under production would remain in the field, and at these sites there would be no impact on soils. New plantings of GT alfalfa would require a permit. Under No Action, there would be no potential for the conversion of conventional agricultural systems (alfalfa or other crops) to commercial GT alfalfa fields. This could preclude an increase in the amount of acres managed using conservation tillage and no tillage systems and may result in adverse impacts to soils compared to the action alternatives. Possible impacts under No Action for those areas that do not contain GT alfalfa may include increased soil erosions, decreased organic matter in soils, and disturbances to soil microorganisms.

Preferred Alternative

2. Impacts on Climate and Air Quality

The deregulation of GT alfalfa and the increase in acres of GT alfalfa cultivation is expected to result in greater amounts of glyphosate herbicide application and a decrease in the mechanical tillage of alfalfa fields.

Because glyphosate is not volatile (evaporating readily) at normal temperatures and is not considered an atmospheric contaminant, the deregulation of GT alfalfa is not expected to result in adverse impacts to air quality. If glyphosate is applied aerially, the risk of drift through the air increases, but this can be minimized by limiting aerial application on GT alfalfa. Approximately 2 percent of glyphosate is applied aerially in the United States (EPA, 2009).

Because the use of glyphosate as a post emergence herbicide is expected to result in an increase in no till farming, a corresponding decrease in the use of mechanical tilling by tractors and other equipment would result under if GT alfalfa were deregulated. Emissions related to global warming, ozone depletion, summer smog and carcinogenicity, among others, were found to be lower in GT crop systems than conventional systems (Bennett et al., 2004). Therefore, full deregulation would lead to a small, positive impact on air and climate.

No Action Alternative

Under the no action alternative, for those 200,000 acres currently planted with GT alfalfa, there would be an increase in the amount of glyphosate applied, as well as a decrease in mechanical tillage of GT alfalfa fields. For new, regulated plantings of GT alfalfa, there would be little increase in the amount of glyphosate applied for the cultivation of alfalfa because new plantings of GT alfalfa would be limited for research and require a permit. This would result in no changes from current conditions to air quality, and no changes in air pollution and greenhouse gases made possible by shifting from tillage to no till practices. There is also no change in the type of herbicides applied, either by ground or aerial application. Therefore, there is a possibility that the no action alternative would result in slightly higher adverse impacts to air pollution and greenhouse gas emissions.

3. Impacts on Water and Water Use

a. Surface Water

Preferred Alternative

Deregulation of GT alfalfa would lead to the increased application of glyphosate herbicides, and a decrease in the application of other, more toxic herbicides, in alfalfa cultivation. Herbicides that adsorb strongly, such as glyphosate, will be protected from degradation and volatilization, and will not readily leach to groundwater. Glyphosate will be found in surface water runoff when erosion conditions lead to the loss of surface particles. However, deregulation of GT alfalfa would likely lead to an increase in conservation tillage and no tillage systems, which would result in less mechanical disturbance of the soil during alfalfa cultivation and

thereby decrease the loss of surface soil. Because of this and the fact that glyphosate binds strongly to soil particles, no tillage and conservation tillage could mitigate the increased application of glyphosate by decreasing glyphosate-laden soil particle in surface water runoff (Wiebe and Gollehon, 2006).

GT alfalfa could provide additional benefit to the water bodies fed by surface waters by encouraging the adoption of conservation tillage and no tillage practices in alfalfa cultivation, thereby reducing erosions and decreasing the amount of sediments in rivers and streams. Sedimentation increases the turbidity (cloudiness of the water due to suspended particles) of water bodies, reducing light penetration, impairing photosynthesis and altering oxygen levels, which can cause a reduction food sources for some aquatic organisms. Sedimentation can also cover spawning beds and impact fish population levels. Phosphorous (a major component of fertilizer) bound to soil particles can be transferred to lakes and rivers via soil erosion, giving rise to high levels of phosphorous in surface waters, which may lead to algal blooms that can impact desirable fish populations.

Additionally, the conversion of conventional alfalfa to GT alfalfa would lead to a shift away from other herbicides toward glyphosate for weed control. As described in chapter 4.E.5., the other herbicides used on alfalfa have varying chemical fates, but, in general, most were more persistent and were characterized by higher mobility in soils, making them more apt to continually contaminate surrounding water systems.

No Action Alternative

Under the no action alternative, no impacts to surface waters are expected to result from the increased application of glyphosate and the resulting contamination of surface waters from glyphosate runoff. Other herbicides will still cause impacts to surface waters. However, the no action alternative would not change the amount of agricultural land managed by conservation tillage and no tillage systems and would result in any of the potential benefits to surface waters associated with this practice, except areas near to the 200,000 acres currently planted to GT alfalfa. In this respect, the no action alternative may lead to increased impacts to surface waters due to increased sedimentation and turbidity.

b. Groundwater

Preferred Alternative

Because glyphosate binds strongly to soil, and its low potential to leach into groundwater, deregulating GT alfalfa is not likely to have an adverse impact on groundwater. It is possible that the reduction in number and

type of other herbicides resulting from a transition from conventional to GT alfalfa, could potentially reduce negative impacts on groundwater from those herbicides; however, no studies have been produced to substantiate such a conclusion.

No Action Alternative

Under the no action alternative there would be no change to the impacts on groundwater associated with the cultivation of alfalfa. However, the possibility exists that the no action alternative would inhibit the shift away from herbicides used on conventional alfalfa towards the more environmentally benign glyphosate on those lands not currently under production of GT alfalfa. The continuing use of more toxic herbicides, instead of glyphosate, could result in a more environmentally harmful contingent of herbicides in groundwater; however, no studies have been produced to substantiate this conclusion and more analyses are needed before this relationship can be analyzed in detail.

H. Mitigation Measures

1. Introduction to Mitigation Measures

As defined in the CEQ regulations implementing NEPA (sec. 1508.20) mitigation includes:

- avoiding the impact altogether by not taking a certain action or parts of an action;
- minimizing impacts by limiting the degree or magnitude of the action and its implementation;
- rectifying the impact by repairing, rehabilitating, or restoring the affected environment;
- reducing or eliminating the impact over time by preservation and maintenance operations
- during the life of the action; and
- compensating for the impact by replacing or providing substitute resources or environments.

This analysis has determined that the proposed action of granting nonregulated status to GT alfalfa would not result in significant adverse impacts to the human or natural environment. The measures listed below, if employed, would lessen adverse impacts associated with the proposed action. However, not employing the methods would not result in significant impacts to the human or natural environment. Furthermore, because GT alfalfa is unlikely to pose a plant pest risk and thus, APHIS has no authority to continue to regulate it, APHIS likewise does not have the regulatory authority to require any mitigation measures be imposed on the deregulated GT alfalfa lines. See chapter 4.B through 4.G for a

discussion of specific impacts resulting from the action alternatives. A summary of mitigation measures are presented by resource area below.

2. Mitigation Measures by Resource Area

a. Measures to Minimize Gene Flow

- If the glyphosate tolerance trait moves from GT alfalfa events J101 and J163 to other alfalfa populations in the United States, these individuals, should they arise and where they require control, could be controlled using other available chemical and/or mechanical means.
- Seed growers undergo training and must be licensed to grow GT alfalfa seed.
- Any farmer who purchases GT alfalfa seed for producing hay is required to sign and comply with a mandatory MTA, and although this requirement is not verified by APHIS, APHIS assumes that growers will fulfill their contractual obligations associated with growing GT alfalfa and that Monsanto and FGI will effectively monitor and enforce compliance with their mandatory MTA and Best Practices. The FGI Best Practices for seed growers is the primary mechanism for limiting gene flow. Features of the MTA and FGI Best Practices are as follows:
 - GT alfalfa seed producers may not sell seed to any party other than FGI and growers may not save seed for any purpose.
 - Bee hives cannot be moved out of GT alfalfa until pollination is finished for the year. This prevents pollen being carried via hive between GT and non-GT alfalfa. Grower must indicate main pollinator species on the FGI Seed Grower Contract.
 - Isolation through distance from other alfalfa fields is required. For pollination with leafcutter bees the distance must be greater than or equal to 900 feet, for Alkali bees greater than or equal to 1 mile, for honey bees greater than or equal to 3 miles.
 - FGI reports seed field location and planting date to local seed certifying organizations, which GT-sensitive farmers can refer to in order to certify isolation distances.
 - Stand removal and volunteer management must be sufficient to allow seed certification inspectors to validate stand removal. Stand removal date and method must be reported to FGI and verified.
 - Cleaning requirements for equipment are included in the FGI Best Practices.
 - The Monsanto MTA requires hay growers to harvest at or before 10 percent bloom.
 - The establishment of barriers between fields can mitigate gene flow. Types of barriers can include bodies of water, or other, more attractive plants for bee foraging in between fields. A border of plants at field edges has the benefit of being a buffer

zone, as pollen would be deposited in the border population before leaving a GT alfalfa field.

b. Measures to Reduce Volunteer Alfalfa and Glyphosate Resistance in Weeds

- Less than 100 percent alfalfa stand termination can result in volunteer alfalfa plants in the following crop. Therefore, good stand termination procedures would be an appropriate method of eliminating volunteer GT alfalfa plants.
- The best way to prevent weed shifts is to avoid using the same herbicide year after year, rotate herbicides and crops, and include non-herbicide strategies to control weeds.

c. Measures to Minimize Impacts to the Biological Environment

- Impacts to threatened and endangered (T&E) plants could be mitigated by maintaining application rates below 3.5 lb a.e./A for ground-based application and 0.7 lb a.e./A for aerial application in the counties where listed species would be within 250 feet of GT alfalfa fields. The maximum single use application rate for ground and aerial applications of glyphosate on GT alfalfa is 1.55 lb a.e./A.
- Aerial applications of glyphosate to GT fields can be minimized to mitigate the risk of herbicide drift to non-target plant species. It is estimated that only 2 percent of glyphosate use would be conducted aerially in GT alfalfa.
- Conservation tillage and no tillage practices have the potential to mitigate impacts to aquatic plants through decreasing runoff loaded with glyphosate.
- Conservation tillage and no tillage practices can mitigate the impacts to amphibian habitat by resulting in decreased soil erosion, decreased sedimentation and herbicide residue in runoff, and decreased turbidity in ponds, lakes, and rivers fed by surface waters.

d. Measures to Minimize Impacts to the Physical Environment

- Conservation tillage and no tillage practices likely to be implemented with GT alfalfa also have the potential benefit of mitigating potential minor effects on soil biological/chemical properties because it leads to enhanced organic carbon and plant residues in surface soils.
- No tillage and conservation tillage could mitigate adverse impacts to surface water associated with increased application of glyphosate by decreasing glyphosate-laden soil particles and general sedimentation and nutrient loading in surface water runoff.

I. Other Impacts

1. Unavoidable Impacts

The preferred alternative is the deregulation of GT alfalfa events J101 and J163 under the regulations at 7 CFR part 340 and once deregulated, these GT alfalfa lines can be grown anywhere in the United States. Under the no action alternative, APHIS would not deregulate GT alfalfa events J101 and J163, and they would continue to be a regulated article and permits issued by APHIS would be required for new introductions of J101 and J163 plants. The preferred alternative of granting nonregulated status to GT alfalfa would result in an increase in the amount of GT alfalfa produced in the United States and a corresponding increase in the prevalence of the gene product in the environment. This would also result in a change in alfalfa cultivation and management practices such as tillage practices and herbicide use, which have implications for the human environment. However, if APHIS determines that GT alfalfa does not pose a plant pest risk, then APHIS has no regulatory authority to deny the deregulation of GT alfalfa events J101 and J163; likewise, APHIS would have no regulatory authority or basis to deny the deregulation of the GT alfalfa based on those potential environmental effects of any increase in the amount of GT alfalfa produced in the United States, a corresponding increase in the prevalence of the gene product in the environment, and a potential increase in glyphosate use. See chapter 4.B through 4.G for a discussion of specific impacts resulting from the action alternatives. As described in chapter 4.C, 4.E, and 4.G, the preferred alternative may diminish certain agricultural impacts due to a shift to more environmentally benign herbicide regimes and conservation tillage practices, but only in the instances that GT alfalfa farming directly replaces non herbicide-tolerant crops and that conservation tillage is adopted in GT alfalfa cultivation. GT alfalfa events J101 and J163 are unlikely to pose plant pest risks (USDA, APHIS, 2009). Therefore, APHIS would no longer be able to regulate GT alfalfa events J101 and J163.

2. Short-term Versus Long-term Productivity

The National Environmental Policy Act (NEPA) states in section 102 (42 U.S.C. 4332) that all agencies of the Federal government shall:

(C) include in every recommendation or report on proposals for legislation and other major Federal actions significantly affecting the quality of the human environment, a detailed statement by the responsible official on --

(iv) the relationship between local short-term uses of man's environment and the maintenance and enhancement of long-term productivity,...

This portion of the NEPA regulations recognizes that short-term uses and long-term productivity of the environment are linked, and that opportunities that are acted upon have corollary opportunity costs in terms of foregone options and productivity that could have continuing effects

well into the future. The preferred alternative and the no action alternative are not likely to adversely affect the relationship between short-term uses and long-term productivity on the resource categories discussed in this EIS, chiefly due to the low likelihood of short-term impacts on these resources resulting from deregulating GT alfalfa. In fact, it is likely that the preferred alternative would result in an increase in the long-term productivity of alfalfa cultivation and would have no significant adverse impact or may even have a small positive impact on the short-term uses of the environment.

3. Irreversible Commitment of Resources

Irreversible resource commitments represent a loss of future options. It applies primarily to the use of nonrenewable resources and to factors that are renewable only over long time spans. An irretrievable commitment of resources represents opportunities that are foregone for the period of the proposed action. It relates to the use of renewable resources, such as timber or human effort, as well as other utilization opportunities that are foregone in favor of the proposed action. NEPA section 102 (42 U.S.C. 4332) and Council on Environmental Quality (CEQ) regulations (40 CFR 1502.16) require that all agencies of the Federal government shall:

(C) include in every recommendation or report on proposals for legislation and other major Federal actions significantly affecting the quality of the human environment, a detailed statement by the responsible official on --

(v) any irreversible and irretrievable commitments of resources which would be involved in the proposed action should it be implemented.

Implementation of the preferred alternative would result in the commitment of natural and man-made resources as the amount of GT alfalfa cultivated in the U.S. would increase. However, this would not represent a significant change over the level of present commitment of resources, nor would it be irreversible. For example, while an increase in the amount of GT alfalfa planted would require more acres of land for agricultural cultivation, data does not indicate that this would result in an irretrievable loss of undisturbed area. It is expected that much of the land that would be used for GT alfalfa cultivation under the deregulation alternative is presently used for agricultural production. Additionally, the overall land devoted to alfalfa is more closely linked to the price of alfalfa hay than it is to the availability of GT technology.

The adoption of the preferred alternative will lead to the increase in the use of glyphosate. The manufacture of glyphosate herbicides would require material and energy inputs, which can be considered irreversible commitments. However, the net impact on these resources is likely to be small, because the use of glyphosate would result in a shift away from other herbicides which also require similar inputs in their manufacture.

There is scientific disagreement over how the overall amounts of herbicide applications change in GT crop systems.

4. Cumulative Impacts

This section describes potential cumulative impacts in connection with deregulating GT alfalfa events J101 and J163. APHIS considered potential impacts of the preferred alternative reported above in chapter 4 of this EIS in combination with the potential impacts of other relevant past, present, and reasonably foreseeable future actions that may have an impact on the same resources. These combined impacts are called cumulative impacts.

Council on Environmental Quality (CEQ) regulations (40 CFR 1500 to 1508) that implement the procedural requirements of the National Environmental Policy Act (42 U.S.C. 4321 et seq.) (NEPA) require a cumulative impacts analysis of the action as part of the environmental impact statement (EIS) process. CFR 1508.7 defines cumulative impacts as:

[T]he impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time.

In this section, actions that could have effects that coincided in time and space with the effects from the proposed deregulation and associated activities are identified and considered in combination with the impacts of other federal, non-federal, and private actions.

a. Structure of the Cumulative Impacts Analysis

For this EIS, the analysis of cumulative impacts follows the analysis steps described in *Considering Cumulative Effects Under the National Environmental Policy Act* (CEQ, 1997):

- Specify the class of actions for which effects are to be analyzed.
- Designate the appropriate time and space domain in which the relevant actions occur.
- Identify and characterize the set of receptors to be assessed.
- Determine the magnitude of effects on the receptors and whether those effects are accumulating.

b. Class of Actions to be Analyzed

This analysis addresses large, regional and national-scale trends and issues that have impacts that may accumulate with those of the preferred alternative. This analysis does not evaluate site-specific cumulative impacts, primarily due to the speculative nature of when, where, and for what duration GT alfalfa may be cultivated if deregulated under the preferred alternative.

c. Geographical and Temporal Boundaries for the Analysis

As discussed in chapter 2 (preferred alternative), APHIS is proposing the deregulation of GT alfalfa without geographic restrictions other than those mandated at the municipal and state level. GT alfalfa has been cultivated in 1,552 counties in 48 States after it was deregulated in 2005. Therefore, the spatial domain for past, present, and reasonably foreseeable future actions considers the entire nation and in some cases, has international implications. This analysis focuses more on geographic interaction of projects than timing of interactions because the actual timeframes for many of the reasonably foreseeable future actions are uncertain.

APHIS considers reasonably foreseeable actions as those future actions for which there is a reasonable expectation that the action could occur, such as the preferred alternative under analysis, a project that has already started, or a future action that has obligated funding. APHIS has identified activities relevant to the cumulative impacts analysis from reviews of information available from government agencies, such as environmental impact statements, land-use and natural resource management plans, and from private organizations. Not all actions identified in this analysis would have cumulative impacts on all resource areas.

d. Resources Analyzed

Resources evaluated in this cumulative impacts analysis include the resource areas discussed in chapters 3 and 4: Biological; Socioeconomic; Human Health and Safety; Land Use and Production Practices; and Physical Environment. However, as discussed in chapters 4.B through 4.G, the preferred alternative is not expected to result in adverse impacts on all resource areas. Resources that would experience impacts from the deregulation of GT alfalfa in combination with other actions are described, and an analysis of the cumulative effects to the resource is presented below.

e. Magnitude of Effects on Resources

The potential extent of the impacts of the preferred alternative combined with other actions, and the duration of those impacts are considered in determining the magnitude of cumulative effects that impact each resource area. When possible, the assessment of the effects on a resource is based on quantitative analysis, however, many effects are difficult to quantify. In these cases, a qualitative assessment of cumulative impacts is made. The approach taken for this cumulative impact analysis is consistent with the intent of CEQ regulations at 40 CFR 1502.22—incomplete or unavailable information. This regulation directs agencies how to proceed when evaluating effects on the human environment in an environmental impact statement when there is incomplete or unavailable information. While information describing the characteristics and potential effects of other projects and activities within the time and space domain is primarily qualitative and in some cases is incomplete or unavailable, there is enough information to consider the cumulative effects of the deregulation of GT alfalfa. This qualitative approach is used when necessary throughout this section and for each resource area. It can be assumed that if a topic is not discussed or is discussed qualitatively, further details about the topic are either incomplete or unavailable.

As suggested by the CEQ (1997) handbook, *Considering Cumulative Effects Under the National Environmental Policy Act*, this EIS considered the following basic types of cumulative effects that might occur due to the preferred alternative:

- *Additive*—loss of a resource from more than one incident.
- *Countervailing*—adverse effects are compensated by beneficial effects.
- *Synergistic*—total effect is greater than the sum of effects when considered independently.

In the following analysis, cumulative impacts should be considered additive unless designated as otherwise. In the case of most resources that may experience cumulative impacts, the preferred alternative is only responsible for a contribution of an incremental portion the total impact on the resource. The past, present, and reasonably foreseeable connected actions typically contribute to the majority of impacts experienced by the resource, and would continue to have impacts on the resource even if the no action alternative were implemented.

5. Analysis of Cumulative Impacts by Resource Area

a. Biological Impacts

As discussed in chapter 4.C, the preferred alternative has the potential to result in impacts to biological resources; either directly from the GT alfalfa events J101 and J163, or indirectly from the associated application of glyphosate herbicide formulations and its accumulation in the environment. Although no significant adverse impacts are expected as a result of GT alfalfa events J101 and J163, the preferred alternative is expected to lead to the increased use of glyphosate herbicide formulations.

Previous GT crops that have been granted nonregulated status include GT sugarbeet, GT corn, GT cotton, and GT soybean. In 2009, approximately 115,000,000 acres of herbicide-tolerant crops were planted, mostly glyphosate- or glufosinate-tolerant corn, cotton or soybean. There are approximately 200,000 acres of GT alfalfa currently planted. Herbicide-tolerant corn and cotton constitute up 48 percent of the total acres devoted to those respective crops, and herbicide-tolerant soybean comprises 91 percent of the soybean acres planted in 2009. Approximately 59 percent of the sugarbeet crop in the United States is tolerant to glyphosate (roughly 650,000 acres), and adoption in 2009 has been estimated to be 95 percent

(<http://www.ers.usda.gov/Briefing/sugar/background.htm>). Almost 21,000,000 acres of alfalfa were grown in the United States in 2009 (USDA-NASS 2009). In the future, if GT alfalfa were grown on half of all alfalfa acres in the United States, GT alfalfa would constitute approximately 10,500,000 million acres. If the acreage currently planted to herbicide-tolerant crops were to remain the same, approximately 8 percent of the herbicide-tolerant acreage grown in the United States would be GT alfalfa. However, there is no data available to suggest the GT alfalfa would reach 50 percent market share, or be more than 50 percent market share.

In 2005, the amount of glyphosate used on GT soybean during the year was 63 million pounds (a.e.) (Kleter et al., 2007). A study conducted by Purdue University found that approximately 42 percent of 1,200 GT corn growers surveyed used 2 post-emergence applications of glyphosate on GT corn, and up to 76 percent may use a preplant or burndown application of glyphosate (Givens et al., 2009). Using 3 application of glyphosate as an estimate for the United States, in 2005 GT corn received 47 million pounds of glyphosate (a.e.). In GT cotton, approximately 40 percent of growers surveyed in 2005 used 3 post-emergence applications of glyphosate (Givens et al., 2005). If three post-emergence and one preplant or burndown application of glyphosate was used in 2005 in GT cotton, approximately 17 million pounds of glyphosate (a.e.) was used in 2005. Thus, perhaps as much as 127 million pounds of glyphosate (a.e.) were applied in 2005 to GT corn, cotton, and soybean. (This estimate is not an

estimate for the pounds of glyphosate used in the environment; only an estimate for glyphosate use on highly-adopted GT crops in 2005. Glyphosate is used extensively in other agricultural, non-GT crops, lawns, nurseries, forestry, and for restoration of habitat.) Estimating for GT alfalfa, if two applications of glyphosate were applied to GT alfalfa, and GT alfalfa comprised 50 percent of all alfalfa acreage (with no increase in alfalfa acreage over the years), the pounds of glyphosate used on GT alfalfa would be approximately 15.6 million pounds of glyphosate (a.e.), or approximately 12 percent of the glyphosate used in GT crops. In comparison, if glyphosate is used extensively in non-GT alfalfa as a burndown application, a single year use of glyphosate in non-GT alfalfa in 2005 could be as high as 37 million pounds (a.e.). However, that calculation assumes that all non-GT alfalfa would be rotated to a different crop in the same year.

APHIS does not have the authority under the Plant Protection Act to regulate herbicide use associated with GT plants that are granted nonregulated status. The use of glyphosate is regulated by the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) restrictions administered by the EPA, which mandate registration and use of all pesticides. EPA includes instructions and restrictions on how glyphosate herbicides can be applied, and has determined that there is no unreasonable environmental risk when used according to the label directions. Violators of the regulations are liable for all negative consequences of their actions, therefore, farmers who use glyphosate are very likely to follow its label restrictions, and adverse impacts from the predicted increased glyphosate use will be minimized. The discussion throughout this cumulative impacts section is based on the assumption that even in the context of FIFRA regulations and label restrictions, there is a chance that glyphosate use would nonetheless result in environmental impacts. This biological impacts section discusses the adverse impacts on plants—threatened and endangered as well as non-target plants—and potentially, amphibians.

The past actions that relate to the cumulative impact of the deregulation of GT alfalfa on biological resources include the deregulation of other GT crops and the shift in herbicide regimes to glyphosate formulations. Glyphosate was first introduced as an herbicide under the trade name of Roundup® by Monsanto in 1974. No calculations or speculation on GT alfalfa's specific impact on herbicide usage have been published, however data are available on the amount of glyphosate applications to GT crop systems in general. Glyphosate use increased more than six-fold between 1992 and 2002, to become the most used herbicide in the United States, mostly due to approval of several GT crops (Gianessi and Reigner, 2006). The transgene responsible for glyphosate tolerance was first introduced in soybeans in 1996, and has been commercialized in several other crops

including cotton, sugarbeet, rapeseed, and corn (http://www.aphis.usda.gov/brs/not_reg.html). Glyphosate usage on GT crops would be dependent on the weather conditions, weed profile, and various other stochastic factors.

As GT alfalfa is adopted, it is expected that glyphosate herbicide will replace other forms of weed control currently used in alfalfa, based on historical information. Using soybeans as an example, the high percentage of adoption of plants engineered for herbicide tolerance (>91 percent of soybeans in the United States in 2009 were herbicide-tolerant) illustrates the shift in herbicide use away from other herbicides and towards glyphosate herbicide formulations (Kleiter et al., 2007). However, as discussed in chapters 3.D.2 and 4.E.5, the actual impact of glyphosate-tolerant crops on herbicide use has not been unanimously concluded. A few studies have claimed that the volume of herbicide use is greater due to GT crops (Benbrook, 2004), while other studies demonstrate a decrease on overall herbicide usage related to the increased use of herbicide resistant crops (Fernandez-Cornejo, 2006; Gianessi and Reigner, 2006; Sakula, 2006; Johnson et al., 2008; Hiemlich et al., 2000).

Benbrook (2004) determined that genetically engineered corn, soybeans, and cotton have led to a 138 million pound increase in herbicide use since 1996, which is a 5 percent increase. According to his calculations, across all crops, genetically engineered crops reduced pesticide use from 1996 to 1998, but from 1999 to 2004, pesticide use increased.

Others have noted that using glyphosate has resulted in the replacement of herbicides that are at least three times as toxic and persist in the environment almost twice as long as glyphosate, (Gianessi and Carpenter, 2000). Trewavas and Leaver (2001) conducted an analysis which revealed that 3.27 million kg of other herbicides have been replaced with 2.45 million kg of glyphosate in soybean fields in the United States. Gianessi and Reigner (2006) noted that an increase in glyphosate usage coincided with a decrease in aggregate amount of herbicide usage by 61 million pounds (of active ingredient) between 1997 and 2002. Much of this reduction occurred in cotton and soybeans, where several herbicides were replaced by glyphosate.

Figure 4-4 (Kleiter et al., 2007) presents the change in herbicide active ingredient per hectare for U.S. GT soybean production.

Figure 4-4. Herbicide use in soybeans, percent of total acres, 1995-2005.

As described in chapter 3.B.2, when exposed to glyphosate, or other herbicides, plant species experience high levels of toxicity. When sprayed with glyphosate, plants that use the shikimate pathway to produce aromatic amino acids will experience toxic effects as they metabolize glyphosate. These toxic effects could include the inability to: (a) photosynthesize; (b) complete respiration; and (c) synthesize nucleic acids and amino acids. Although the effects can be slow to progress, all of these toxic effects could result in plant death.

Under the preferred alternative, plant species—including threatened and endangered species—found in the vicinity of GT alfalfa crops may be at risk for increased exposure to glyphosate and a potential for decreased exposure to other herbicides, even though the exposure would be limited if the label use restrictions are followed. Also, human actions such as changes to transportation and energy infrastructure, urban and suburban development, conversion of land for agricultural use, and resource extraction, have the potential to negatively impact plant species, as the actions result in the decrease of available habitat for the plants. The ongoing impacts of widespread human activities resulting in habitat loss, along with the incremental effect of increased exposure to glyphosate resulting from the preferred alternative, could result in cumulative impacts to plant species. These same effects are possible with other future actions resulting in habitat degradation and could result in adverse cumulative impacts on plant populations when combined with the incremental impacts resulting from the preferred alternative. Future actions that could result in habitat degradation include increased pollutant accumulation in the soil over time due to various point and non-point sources, topsoil erosion and runoff from future development (housing or other) and/or pressure from the introduction of invasive species.

The deregulation of other GT crops could also result in cumulative effects to plants. Petitions for Nonregulated Status are pending for GT corn and

creeping bentgrass (http://www.aphis.usda.gov/brs/not_reg.html). If deregulated, the production of these GT crops would lead to increased glyphosate application, and in the instances that it is cultivated in or near the same geographic areas where GT alfalfa is produced, this could lead to a cumulative impact on plants affected by the preferred alternative. In addition, in 2009, GT sugarbeet was commercial grown for the first time. The impact of GT sugarbeet on the cumulative use of glyphosate is minimal, however, because of the relatively small acreage devoted to sugarbeet (less than 1 million acres). For comparison, there are 20 million acres of available alfalfa production which could be converted to GT alfalfa. Additionally, current soybean acreage is 74 million acres, of which over 90 percent (66.6 million acres) are grown using GT soybean (USDA–NASS, 2009).

Legally mandated label use restrictions should decrease the likelihood of these cumulative impacts of increased glyphosate use. Predicting potential cumulative impacts is difficult due to the dynamics of other factors that come into play. For example, cumulative impacts are not likely to occur unless aerial drift or surface water runoff from GT alfalfa and other GT fields reach the same plant species. Even under these circumstances it is unlikely that cumulative impacts to any given plant populations would result unless fields of GT alfalfa and other GT crops were located adjacent to each other, label restrictions were not observed, the decreased use of other, less toxic herbicides did not result in the protection of some plant species, and no other herbicides were used in agricultural production.

The likely adoption of conservation tillage practices in GT alfalfa production (described in chapter 4.C.2.) has the potential to decrease glyphosate-laden sedimentation in surface water runoff, and would lessen some of the impacts of the preferred alternative on plants. Also, practices in application of glyphosate (observing the legally-mandated maximum aerial and ground-based application rates that are governed by FIFRA regulations) would likely decrease the amount of drift and lessen the impacts of the preferred alternative on T&E and nontarget plant species. Either of these could result in a decrease in the incremental impacts on plants due to the preferred alternative, and could, therefore, lower the net cumulative effect of the other actions described above.

Glyphosate is only slightly toxic to amphibians and is not expected to be a risk to amphibian populations. However, amphibians exhibited greater sensitivity to Roundup® formulations than to glyphosate tested as an acid or IPA salt. This could be due to the surfactant (POEA) used in agricultural formulations, which has been found to be potentially more toxic to amphibians and other aquatic animals than the herbicide itself (Lajmanovich et al., 2003). Some researchers have suggested that Roundup® (in combination with POEA, specifically Roundup® Weed and

Grass Killer used in this study) could cause high rates of mortality to amphibians that could lead to eventual population declines (Relyea, 2005). However, the testing methods of this study have been called into question due to the high exposure doses, which exceed application rates of glyphosate, as well as the fact that this Roundup® product is not approved for use in an aquatic setting. Additionally, the impacts of the preferred alternative on amphibians are unlikely because Roundup® Weed and Grass Killer (the glyphosate formulation hypothesized to affect amphibians) is not approved for use on Roundup® Ready Alfalfa. Therefore, the preferred alternative should not result in an increase in the use of this particular product. However, there is a remote possibility that these products may be used on GT alfalfa fields, so their impact cannot be ruled out entirely.

Correspondingly, glyphosate itself is slightly toxic to fishes and aquatic invertebrates, but toxicity data suggest certain surfactants in glyphosate formulations result in a higher toxicity. For GT alfalfa use, glyphosate exposure does not result in risk exceeding levels of concern for fishes or aquatic invertebrates; however, the end use herbicide concentration (Roundup ®) could not be estimated to enable a quantitative risk assessment. Therefore, impacts to fishes and aquatic invertebrates resulting from the preferred alternative cannot be determined. As is the case with amphibians, this does not preclude the possibility that the surfactants found in the end-use herbicide could result in adverse impacts on fishes and aquatic invertebrates.

Habitat loss and degradation are by far the greatest threat to amphibians, fishes, and aquatic invertebrates at present. Habitat loss and degradation can result from several broad classes of actions. These include:

- grazing, logging, mining, and other extractive industries;
- pollution and pesticide use (including pH and metals toxicity);
- dams, other water diversions, and water extraction;
- transportation and energy infrastructure development; and
- urban and suburban development.

In the case of impacts to amphibians, fishes, and aquatic invertebrates, the above activities have the potential to contribute cumulatively to adverse impacts. Glyphosate-laden agricultural water runoff (a minimal effect if label use restrictions are followed) would place an additional stress on populations that could be affected by, ongoing habitat loss leading to smaller populations in the watershed (area of land where all the water that is under it or drains off of it goes into the same place) where the preferred alternative could occur

(<http://www.epa.gov/owow/watershed/whatis.html>). However, the shift to glyphosate from more toxic herbicides may lessen any effects that are due

to agricultural water runoff. Widespread habitat degradation from human activities such as housing construction, transportation infrastructure development, and water pollution could also potentially compound the incremental impacts resulting from the preferred alternative's effects on water quality.

Many species of fishes are being affected by over-fishing, which can negatively impact fish populations. The demand for certain species, such as salmon, has continued to increase while population levels have decreased. A possible overall decrease in fish populations due to incremental mortality from exposure to glyphosate and/or other herbicide formulations, combined with ongoing present and future over-fishing impacts, could result in cumulative adverse impacts to commercially and recreationally valuable species. The stress of the preferred alternative on fish populations is minimal when compared to the stress of over-fishing.

It is important to note that the impact to amphibians, fishes, and aquatic invertebrates resulting from the preferred alternative is uncertain. In addition, tillage practices likely to be adopted under the preferred alternative would lessen potential adverse impacts to aquatic amphibian habitat due to the decrease in erosion and sedimentation (see chapter 4.G.3), and decreases in the use of other, more environmentally harmful herbicides. Additionally, adherence to the label restrictions for glyphosate herbicides has been determined not to lead to unreasonable environmental impacts by the EPA. This minimizes, but does not eliminate the environmental risks of the preferred alternatives.

Plants at risk due to the use of glyphosate are at risk due to the use of any herbicide, as herbicides are made to kill plants. Plants and animals that are in alfalfa fields and surrounding alfalfa fields are currently exposed to herbicides that are currently used in conventional alfalfa production, including glyphosate. Glyphosate is likely being substituted for other more toxic herbicides in GT alfalfa production, compared to non-GT alfalfa production. Cumulatively in alfalfa production, glyphosate is a more environmentally preferred herbicide compared to other herbicides currently used in alfalfa production, i.e., generally less toxic and generally metabolizes more rapidly, and may even decrease the potential of negative consequences to plants and animals that may be exposed to other herbicides in alfalfa production. The commercial planting of GT alfalfa is likely to result in the cumulative increased use of glyphosate. EPA has the regulatory authority to register herbicides and has determined that there is no unreasonable harm to the environment when label restrictions for glyphosate are followed. Additionally, APHIS is not aware of any data indicating that such a cumulative increase in the use of glyphosate will amount to a significant impact on the environment.

b. Socioeconomic Impacts

Glyphosate-Resistant Weeds

GT alfalfa deregulation would likely lead to increased use of glyphosate, in addition to the increased use already fostered by past deregulation of other GT crops, and the decrease of other herbicides used in alfalfa production. If the increased use of glyphosate leads to an increase in the presence of glyphosate-resistant weeds in GT alfalfa—as well as in crops with which GT alfalfa is rotated—then glyphosate would have to be substituted or complemented in farming by other herbicides.

Furthermore, if GT alfalfa is widely adopted in areas where it is a major crop, the potential that alfalfa acreage would overlap with glyphosate-resistant weed locations varies across states, depending on the current occurrence of glyphosate-resistant weeds and the acreage devoted to alfalfa. The current use of glyphosate on other deregulated GT crops such as soybean, cotton, sugar beet, rapeseed, and corn in addition to GT alfalfa, represents the use of glyphosate beyond GT alfalfa and would increase the potential of glyphosate-resistant weed development which may occur in GT alfalfa fields as they become more widespread. Also, possible deregulation of other GT crops would mean increased use of glyphosate, may consequently increase the development of glyphosate-resistant weeds. These actions would have an adverse cumulative effect on the ability to use GT alfalfa for weed management, and would also incrementally increase the potential for glyphosate-resistant weed development.

Although the potential for glyphosate-resistant weeds exists in GT alfalfa, it is important to note that there are no studies or data that equivocally demonstrate if GT alfalfa would directly cause the development of glyphosate-resistant weeds, or where glyphosate-resistant weeds would occur in the environment if GT alfalfa was deregulated, or how widespread glyphosate-resistant weeds would be if GT alfalfa would be deregulated. As stated previously, although GT alfalfa is likely to result in an increased use of glyphosate; that increased glyphosate use does not immediately or directly result in glyphosate-resistant weeds. Because GT alfalfa is a perennial, and the production of GT alfalfa includes mowing, these biological and production characteristics may result in delayed or non-existent glyphosate-resistant weed development and/or delayed or non-existent weed shifts if GT alfalfa is deregulated.

If there are glyphosate-resistant weeds in GT alfalfa fields that require the use of other herbicides for control of such weeds, this would most likely result in an increase in production costs for GT alfalfa. However, the production costs would still most likely be lower than the present

conventional system. In a worst-case scenario, GT alfalfa would be treated as in a conventional system and result in alfalfa hay of quality similar to that of a conventional system. The price of GT alfalfa seed would likely be reduced for the survival of the variety in the market. Another unknown is the availability and environmental profile of new herbicides that may enter the market, and may provide an additional alternative for glyphosate-resistant weeds.

There is some literature on the costs of herbicide use in GT crops that have been previously deregulated. An increase in herbicide costs over time would likely reflect cost effects of increased presence of glyphosate-resistant weeds. However, the existing literature does not indicate that such an increase in costs has occurred to date. Brookes and Barfoot (2005) report that after nine years of GT soybean cultivation, estimates of cost savings actually increased, with savings mostly attributed to reduced herbicide costs. They also report continued cost savings with herbicides in the United States after 8 years of herbicide-tolerant cotton (mostly GT) cultivation and after 6 years of GT canola cultivation.

The continued savings in herbicide costs in GT crops to date does not mean absence of an increase in herbicide resistance, since costs depend not only on the volume of herbicide used but also on prices. It also does not mean increased costs would not still occur in the future. It only means that, to date, there is little evidence of a reversal in the herbicide cost reductions generally identified in GT crops in the United States. It must also be noted that reduced costs with herbicides do not necessarily mean increased economic returns. Fernandez-Cornejo and McBride (2002) noted that the literature on the economic impact of GT soybeans in the United States is mixed, and some farmer surveys show reduced herbicide costs being offset by higher technology fees.

Seed Market Concentration

If acceptance among alfalfa farmers of GT alfalfa is high, there will likely be an increased concentration in the market for alfalfa seed technology. Increased market concentration is often associated with monopoly rents and decreased welfare. Fernandez-Cornejo and Schimmelpenninck (2004) note that the commercial seed market has already gone through a process of consolidation since the early 1990s. The importance of this consolidation is enhanced by the fact that research and development in crop varieties has become mostly a private sector activity in the United States since the late 1980s. Fernandez-Cornejo and Schimmelpenninck (2004) suggest there is some evidence that this market consolidation—in an activity increasingly undertaken by the private sector—has been accompanied by a decrease in the intensity of public

research in crop variety development, suggesting a possible negative impact of market concentration on future research and development.

Feed Costs

A recent USDA document (USDA-ERS, 2008b) suggests feed costs will increase in the coming years due to increased production of corn for ethanol. To the extent that dairy farms are affected by this increase in feed costs, GT alfalfa deregulation may help mitigate these effects by improving the quality of available alfalfa without an increase in costs.

Growth of Organic Markets

Chapter 4.D notes that there is not enough information to predict the impact of GT alfalfa deregulation on organic markets. Any impact, however, will likely be magnified or diminished by the current growth trend in organic markets. As shown in chapter 3, organic alfalfa acreage has grown since 2000. If this growth is associated with a growth in demand for non-GE foods, GT alfalfa deregulation may give additional impulse to the demand for organically certified products. If deregulation increases organic production costs associated with isolation, buffer zones, or relocation, this growth may be slowed.

Export Markets

Deregulation of GT alfalfa could imply losses in exports of alfalfa seed and hay to the main U.S. clients (Saudi Arabia and Japan, for each product respectively). Any losses are unlikely to be regained in the future, since the trust established by lasting commercial relationships is often valued in international trade. The extent of these losses will depend on evolving regulations for trade in genetically engineered crops.

Regulations and markets for GE products are still being largely developed in most countries. In the case of Japan, for example, there is not enough information on whether genetically engineered content in animal feed will become increasingly rejected or accepted by consumers. In the case of an increased rejection, much of this market could be lost, depending on the level of market tolerance (beyond standards) for adventitious presence. In the case of an increased acceptance, the United States may actually benefit from the increased competitiveness of GT alfalfa in a market where competitors (e.g., Australia) are currently gaining ground.

Global Climate Change

Global climate change refers to long-term fluctuations in global surface temperatures, precipitation, ice cover, sea levels, cloud cover, ocean

temperatures and currents, and other climatic conditions. Scientific research has shown that in the past century, Earth's surface temperature has risen by an average of about 1.3 degrees Fahrenheit (°F) (0.74 °C); sea levels have risen 6.7 inches (0.17 meter); Arctic sea ice has shrunk by 2.7 percent per decade, with larger decreases of 7.4 percent in summer, and mountain glaciers and snow cover have decreased (IPCC 2007). Most scientists now agree that this climate change is largely a result of greenhouse gas emissions from human activities. The Intergovernmental Panel on Climate Change (IPCC) recently asserted that, "Most of the observed increase in global average temperatures since the mid-20th Century is *very likely* due to the observed increase in anthropogenic [human-caused] greenhouse gas concentrations" (IPCC, 2007).

A recent U.S. Climate Change Science Program (Backlund et al., 2008) report suggests forage production may benefit from increased temperatures through the lengthening of the growing seasons, but may also be negatively affected by reduced water availability. Precipitation was the main factor determining different predictions of global climate change impacts on alfalfa yields when various studies were compared, with yields more likely to increase in the Pacific Northwest and to decrease in the central regions. The same report suggests both positive and negative effects of global climate change on forage quality are possible and that productivity of dairy cows may decrease with higher temperatures. The quality improvements of GT alfalfa hay may help mitigate some of the potential negative consequences of global climate change on alfalfa and dairy production.

On the other hand, the same report suggests there is some evidence that the effectiveness of glyphosate could be reduced under higher CO₂ levels, and the type of photosynthetic pathway used by weeds (either C₃ or C₄) could play a role.²² Recent research on the impacts of current and increasing CO₂ concentrations in the atmosphere suggest that rising CO₂ concentrations could increase glyphosate tolerance in a C₃ weedy species (Ziska et al., 1999). This finding was supported by another study where a reduction in glyphosate efficacy at higher CO₂ levels was observed concurrently with the stimulation of C₃ weeds in field grown Roundup Ready® soybean (Ziska and Goins, 2006). While in general, relative impacts of increasing CO₂ concentrations have been observed to be greater for C₃ weeds, there have been species –specific responses which demonstrate a range to impacts within C₃ and C₄ weeds. The Ziska and Goins 2006 study on Roundup Ready® soybean concluded that depending on weed species (C₃ vs. C₄), elevated CO₂ can increase weed biomass, decrease yields, and reduce glyphosate efficacy for Roundup Ready® soybean. It is possible that C₃ weeds such as lambquarters and Canada

²² Ziska and Goins (2006) did not investigate the effectiveness of glyphosate under higher CO₂ levels for a third photosynthetic pathway in plants, the CAM pathway).

thistle which are found in GT alfalfa would be affected similarly as CO₂ concentrations increase. This impact of increasing CO₂ concentrations may add to the adverse cumulative effects of development of glyphosate-resistant weeds in GT alfalfa.

Global climate change alone could also result in a cumulative effect to plant species. Global climate change can lead to changes in local and regional temperature and precipitation patterns. When weather has changed to the extent that plant populations are no longer suited to tolerate that area, this can result in population decline, extirpation, or local extinction. Studies have noted the response of biological and chemical characteristics of ecosystems to climate conditions, especially temperature change. Substantial research has examined the effects of climate change on vegetation and wildlife, leading to the conclusion that the changing climate is already having a real and demonstrable effect on a variety of ecosystem types (CCSP, 2008a). As noted in the IPCC report, plants and animals can reproduce, grow, and survive only within specific ranges of climate and environmental conditions (Fischlin et al., 2008). Changes in climate can affect terrestrial ecosystems by shifting range boundaries or densities of individuals within their ranges or causing extirpation or extinction (Rosenzweig et al., 2007).

The potential incremental effect of increased mortality due to glyphosate exposure, combined with larger competition pressures from ongoing species migrating as temperature and precipitation patterns change (Parmesan and Yohe, 2003), could result in substantial population declines or even local extinction of some plant species. However, it is worth noting that the effect of glyphosate use on plant population structure and distribution is small when compared to the impacts of global warming, and the effect of glyphosate use would likely be the same or less than the use of other herbicides. In this respect, global climate change is not to likely magnify the impacts of the preferred alternative, and global climate change, in combination with herbicides more toxic than glyphosate, could still lead to cumulative adverse impacts to plant populations. Historical data for many parts of the United States indicate an increase in the frequency of high-precipitation events (e.g., >5 cm in 48 hours) correlated to global climate change, and this trend is projected to continue for many regions (CCSP, 2008b). This can lead to field flooding, increased sedimentation, and leaching of nutrients and agricultural chemical into surface water. These effects, compounded with the incremental effect of glyphosate runoff expected as a result of the preferred alternative, could also constitute an adverse cumulative effect on aquatic plant species if the comparison was glyphosate use compared to no herbicide use. Again, however, glyphosate is currently used in alfalfa, and is likely to replace other herbicides currently used in alfalfa production if GT alfalfa is deregulated. Thus, the overall cumulative impact of increasing glyphosate

and decreasing other herbicides is likely negligible given the context of conventional agricultural production.

Global climate change may also be affecting amphibian, fish, and aquatic invertebrate populations. While more analysis is needed, the potential impacts of global climate change are clear. Extreme weather events or other factors that would affect the timing of breeding and amphibian life cycles are unlikely to be the primary cause for the observed decline in amphibian populations in many regions. However, global climate change may play an enabling role, or magnify other, more direct causes of mortality for amphibians as well as fishes and aquatic invertebrates (CCSP, 2008b). Although no data are presently available that can be analyzed to determine the combined impact of global climate change and herbicide application on amphibian species, it is possible that the poleward migration of disease agents known to result in increased frog mortality, such as the Chytrid fungus (NSTC, 2008), enabled by a warming climate would have a greater impact on amphibian populations whose vitality has been compromised by exposure to herbicides. Given that glyphosate is less toxic than other herbicides, and would be used instead of more environmentally harmful herbicides in GT alfalfa, it is likely that the increased use of glyphosate in GT alfalfa would have little cumulative effect on amphibians.

A warming climate is expected to increase water temperatures and modify regional patterns of precipitation, and these changes can have effects on water quality. As temperature increases, the ability of water to hold dissolved oxygen declines, and as water becomes anoxic, aquatic species begin to experience suboptimal conditions (NSTC, 2008). This could act in concert with the toxic effects of herbicide exposure to result in adverse cumulative impacts to amphibian, fish, and aquatic invertebrate populations. Given that glyphosate use likely to increase in GT alfalfa, but the use of other more toxic herbicides would likely decrease under the preferred alternative, the cumulative effect of glyphosate use likely be minimal.

Global climate change is also likely to result in increased high-precipitation events throughout the United States (Backlund et al., 2008). An increase of intense rainfall events leading to field flooding would impact amphibians, fishes, and aquatic invertebrates through higher levels of sedimentation and nutrient and chemical leaching in agricultural systems. This has the potential to magnify effects of herbicide use by further increasing the amount of glyphosate accumulation in surface water over what would be expected due to the preferred alternative alone.

Moreover, many fish species depend on spring snowmelt for the water to fill the streams and rivers in which they live and breed. Global climate

change resulting in increase temperatures decreases the amount of winter snowpack (CCSP, 2008b). This can impact the water levels in fish habitat, and may result in an adverse impact to certain fish populations. The potential for cumulative impacts exists if snow-fed streams and rivers are also fed by runoff from GT alfalfa fields. In these cases, the addition of potentially toxic impacts of the herbicide formulations would further impact fish populations already under stress from decreased snowmelt and available habitat. However, the label restrictions for glyphosate should preclude impacts to aquatic habitats.

Previous GT Alfalfa Deregulation Time Period

GT alfalfa was deregulated between June 2005 and March 2007. During this period an estimated 200,000 total acres were planted (Putnam, 2007). This corresponds to 1 to 2 percent of total alfalfa hay acreage. There are no foreseeable cumulative impacts of this deregulation period in the case of alfalfa deregulation. Presumably, the 2005–07 deregulation time period may affect the speed of acceptance of GT alfalfa in the market place, given that some farmers are now familiar with the variety.

Colony Collapse Disorder (CCD)

Incidence of CCD in honey bees emerged in 2007 and the total honey bee population in the United States decreased by 30 percent. Sustained decreases in the honey bee population may affect the cost of pollination, an important cost in alfalfa seed production. Eventual increases in pollination costs will likely be transmitted to seed prices, given that demand for alfalfa seed is highly inelastic (Myer et al., 1998). However, the impact on alfalfa hay farming will likely be minor, given the small participation of seeds on total hay farming costs, and would likely be outweighed by reduced costs from GT alfalfa in the case of deregulation. Sustained incidence of CCD in honey bees could presumably lead to a greater concentration of alfalfa seed production in areas where other bee species, such as alkali bees and leafcutter bees, are more commonly used for pollination. (For more information, see “*Technical White Paper on Colony Collapse Disorder and Glyphosate-Tolerant Alfalfa*” (appendix O)).

Spread of Subspecies “falcata”

Future spreading of the *Medicago sativa* subspecies *falcata*, which is naturalized in the northern and western United States, and is being promoted as a rangeland enhancer for grazing, could result in increased hybridization of *falcata* with GT alfalfa. As discussed in chapter 4.B.4, hybrids with mostly *sativa* parentage are predicted to be hardier than the original GT alfalfa but have less rangeland hardiness than the *falcata*

parent. The *falcata* hybrid possessing the GT trait may potentially become established in rangeland habitats and serve as a reservoir for the GT trait. As the future use of *falcata* increases in rangelands, GT alfalfa seed farmers may have to protect their seed crop from cross contamination with neighboring rangelands. Also, the risk of gene flow from GT fields to organic beef and dairy farmland may increase with the spread of *falcata*. Future spreading of *falcata* may also affect the feral alfalfa populations.

c. Human Health and Safety Impacts

The direct and indirect effects of the deregulation of GT alfalfa to human health and safety are described in chapter 4.E, which concludes that under present and expected conditions of use, glyphosate herbicide does not pose a health risk to humans. Impacts from past actions that add to cumulative impacts related to human health and safety include the past deregulation of other GT crops and the resulting change in herbicide use. As more GT crops were deregulated, glyphosate use increased along with a related decrease in the use of other, more toxic and persistent herbicides (see chapters 4.E.5 and 3.D.2). This impact of other GT crop deregulation, along with the deregulation of GT alfalfa, would result in an increase in exposure to glyphosate for the general public. With more GT crops, there is a greater chance that crops grown for human consumption will be found planted near GT crops, which could result in a greater chance for unintentional glyphosate applications on food crops and a subsequently greater chance for the general public to be exposed. This chance would increase with the deregulation of GT alfalfa. However, glyphosate has been shown to replace more toxic herbicides, so the overall risk to human health, cumulatively, would likely decrease with the deregulation and adoption of GT alfalfa. Thus, the net cumulative result is a likely reduction in the overall exposure to more toxic herbicides for the general public.

There is a risk that the incremental effect of the deregulation of GT alfalfa, when combined with the effect of past deregulation of other GT crops may cumulatively lead to the development of glyphosate-resistant weeds due to the selection pressure of the predominant use of glyphosate. If this happens, farmers would likely adopt herbicide use practices that include different, more toxic herbicides. The risk to human health would then potentially revert to that of current risk assessments based on cultivation of conventional alfalfa.

The Roundup® herbicide (glyphosate) label states that the product can be used for numerous non-crop uses such as airports, apartment complexes, Christmas tree farms, ditches, driveways, dry canals, fencerows, golf courses, greenhouses, industrial sites, landscape areas, municipal sites, natural areas, office complexes, parks, parking areas, pastures, public

areas, railroads, recreation areas, roadsides, schools, sports complexes, storage areas, and wildlife management sites (http://www.monsanto.com/monsanto/ag_products/pdf/labels_msds/roundup_orig_max_label.pdf). The U.S. Forest Service uses glyphosate primarily in conifer release (58.2 percent), noxious weed control (15.5 percent), and site preparation (16.4 percent). Other minor uses (10.3 percent) include hardwood release, facilities maintenance, recreation improvement, right-of-way maintenance, seed orchard protection, wildlife habitat improvement, and other weed control (agricultural, aquatic, or nursery). In 2001, the total annual use of glyphosate by the U.S. Forest Service was approximately 44,700 pounds applied to approximately 19,000 acres, which corresponds to about 0.275 percent of the agricultural use (USDA-FS, 2003). All of these data combines to show that glyphosate is currently a widely-used herbicide, and in numerous applications other than agricultural. The additional incremental increased use of glyphosate that would occur with the deregulation of GT alfalfa, along with the current use as described here, could minimally increase exposure to the general public.

It is not likely that this gene product would be permitted in alfalfa crops grown for human consumption (sprouts) in the near future, but because glyphosate is due for reregistration in 2009, there is a chance that glyphosate regulations may change. However, the exact changes are not known at this time and therefore cannot be incorporated into this analysis. If the regulations do change substantially, then they would have the potential to affect the cumulative impacts of deregulation of GT alfalfa. Global climate change is very likely to have adverse impacts on human health. It is predicted that with global climate change, precipitation levels will increase (Gamble et al., 2008), which could increase runoff and, therefore, increase the chance of contaminating a nearby food crop with glyphosate or with any other pesticide that may have been used.

d. Land Use and Production Practices

The direct and indirect effects of the deregulation of GT alfalfa to land use and production practices are described in chapter 4.F. These include: the expected displacement of other alfalfa varieties where alfalfa is highly managed; the replacement of other forms of weed control with glyphosate; less tillage of soils due to longer stand life; a possible reduction in the amount of nitrogen fertilizers applied; and changes in crop rotation. Factors such as herbicide use, weed resistance, crop rotations, isolation zones and GT alfalfa-free zones all interact cumulatively to impact land use and production practices. However, there are other actions, that when added to the deregulation of GT alfalfa, may cause cumulative impacts to land use and production practices.

The previous deregulation of other GT crops will influence both herbicide use and crop rotations for GT alfalfa. Data and studies have shown that with the introduction of GT crops, glyphosate use has increased and other herbicide use has decreased (see chapters 4.E.5 and 3.D.2). This change in herbicide use that has occurred with other GT crops will most likely continue with the adoption of GT alfalfa. It will encourage the use of glyphosate, as that will be the most cost-effective way of achieving weed-free alfalfa stands. This increased use of glyphosate will replace the use of other herbicides, most of which are more toxic than glyphosate and/or have more negative impacts on the environment than glyphosate. Increased glyphosate use from the preferred alternative would result in an incremental increase in the chance of evolving glyphosate-resistant weeds. If glyphosate-resistant weeds become established in alfalfa, then production practices will revert to those used to manage conventional alfalfa, and growing the crop will once again have those inherent costs. Future deregulation of other GT crops, such as creeping bentgrass or other varieties of corn and cotton, whose proposals for deregulation are pending, would impact land use and production practices in a similar fashion.

The crop rotations necessary for GT alfalfa would be influenced by already deregulated GT crops. Farmers using GT crops are advised to include non-GT crops in rotation, so there may be limitations in the use of other GT crops along with GT alfalfa. The opposite situation is true as well, where the use of GT crops, such as GT corn or GT soybeans, would limit the adoption of GT alfalfa in crop rotations. Farmers must consider these issues when deciding on crop rotations for their fields. Other factors, such as nutrient content and location, would impact crop rotation choices.

Global climate change also has the potential to impact future land use and production practices, as alfalfa cultivation is heavily based on climate. Research has shown that as CO₂ levels increase, as is possible with global climate change, glyphosate loses its efficacy on weeds (Ziska et al., 1999). If this were to happen, then farmers would need to adapt herbicide use and change production practices of GT alfalfa. Thus, climate change may necessitate an increase in the use of glyphosate and could amplify the impacts of the preferred alternative.

e. Physical Environment

As described in chapter 4.G.3, the preferred alternative has the potential to lead to adverse impacts on surface water. This is chiefly due to the chemical fate of glyphosate and its metabolite, which adsorb to soil particles that become suspended in runoff water and can potentially contaminate surface waters as a result of erosion of this soil. Glyphosate will be found in surface water runoff when erosion conditions lead to the

loss of surface soil particles. However, deregulation of glyphosate-tolerant alfalfa would likely lead to an increase in conservation tillage and no tillage systems, which could mitigate the increase application of glyphosate by decreasing sedimentation of glyphosate-laden soil particle in surfac water runoff (Wiebe and Gollehon, 2006). The quality of surface water may also be improved by conservation tillage, as it reduces erosions and decreases the amount of sediments in rivers and streams (see chapters 3.E.5 and 4.G.1 for further discussion on this topic). Additionally, EPA label restrictions result in application rates and practices that have no unreasonable environmental risk.

Past actions contributing to impacts on surface water pollution include agriculture, industry, resource extraction, urban, suburban, and rural development, and other human activities. GT crop systems have led to an increase in the amount of glyphosate herbicide formulations applied in recent years and a decrease in the amount of other herbicides applied.

There are several other actions that have the potential to contribute to cumulative impacts on surface water.

- *Global climate change*—This would lead to high-intensity rainfall events increasing field flooding, sedimentation, nutrient loading, and accumulation of agricultural chemicals in surface waters. The impact of the deregulation of GT alfalfa on surface water would be magnified by high-intensity rainfall events, which could lead to a greater quantity of glyphosate in surface water runoff.
- *Livestock grazing*—Widespread grazing has led to desertification in the western United States, resulting in impacts to surface water via increased sedimentation in runoff. If grazing impacts watersheds that are home to GT alfalfa fields, there is a potential cumulative impact on surface waters due to the sedimentation from grazing, combined with the glyphosate runoff from GT alfalfa.
- *Human activities resulting in non-point source pollution*—These include construction activities, land development, agricultural practices, lawn chemical application, soil erosion, and stormwater runoff. These activities have the potential to cumulatively impact the surface water through sedimentation and pollutants in runoff. If future activities contributing to these impacts occur in watersheds where GT alfalfa is cultivated, there may be potential for adverse cumulative impacts on surface water. Because the impacts would not be a simple incremental increase in the amount of glyphosate in surface water, but would be an interaction of increased glyphosate combined with other pollutants and/or increased sedimentation, the nature of the cumulative impact would be more complex than some of the additive impacts described above.

- *Increase in impervious surfaces*—This has occurred due to the construction of roads, buildings, parking lots, and other impervious structures. This leads to increased quantity and decreased quality of stormwater runoff into watersheds. These actions often have the added effect of removing soil stabilizing vegetation, which increases erosion and sedimentation in water runoff. If future activities contributing to these impacts occur in watersheds where GT alfalfa is cultivated, there may be the potential for adverse cumulative impacts on surface water.
- *Deregulation of other GT crops*—Petitions for Nonregulated Status are pending for GT corn, and creeping bentgrass (http://www.aphis.usda.gov/brs/not_reg.html). If deregulated, the production of these GT crops may lead to increased glyphosate use, and in instances where it is cultivated in the same watersheds where GT alfalfa is produced, this may lead to a cumulative impact on surface water in these areas from glyphosate runoff. GT crops that have been deregulated in the past, such as GT cotton and soybeans, have also led to an increase in the incidence of glyphosate-resistant weeds (USDA, 2008b). As these weeds become more widespread and a problem for GT alfalfa, weed management techniques would adapt in response. Farmers would likely increase their use of mechanical weed control techniques to replace glyphosate use, such as tillage, which could lead to cumulative impacts on surface water from soil erosion and surface water runoff (Fawcett and Towery, 2002).

6. Summary

In conclusion, APHIS examined the cumulative impacts of GT alfalfa and glyphosate use on the biological environment; socioeconomic environment; human health and safety; land use and production practices; and the physical environment. If APHIS were to grant nonregulated status to GT alfalfa lines J101 and J163, any cumulative impact on the human environment attributable to the use of glyphosate would not likely be a significant change to the environment due to the adoption and presence of GT alfalfa plants in alfalfa production. However, in many cases, only a qualitative assessment was conducted due to a lack of available quantitative information.

The past actions that relate to the cumulative impact of the deregulation of GT alfalfa on biological resources include the deregulation of other GT crops and the shift in herbicide regimes to glyphosate. EPA has determined that there is no unreasonable environmental risk when using glyphosate when the user adheres to the label restrictions, as they are legally required to do.

Predicting potential cumulative impacts is difficult due to the dynamics of other factors that come into play. For example, cumulative impacts are not likely to occur unless aerial drift or surface water runoff from both GT

alfalfa fields and other GT fields reach the same plant species, animal species, or sector of the environment. Even under these speculative and hypothetical circumstances, it is unlikely that cumulative impacts to any given populations would result unless fields of GT alfalfa and other GT crops were located adjacent to each other, label restrictions were not observed, the decreased use of other, less toxic herbicides did not result in the protection of some species or environmental attribute, and no other herbicides were used in any agricultural production. Additionally, end use herbicide formulations, including the use of surfactants could not be estimated to enable a quantitative risk assessment. Moreover, the impacts of cumulative use of glyphosate are incrementally small in comparison to the many other much more significant threats to plant and animal species in the environment (such as over-fishing, habitat loss degradation due to grazing, logging, urban and suburban development, transportation and energy infrastructure development, pollution, dams, global climate change, etc.).

If the increased use of glyphosate leads to an increase in the presence of glyphosate-resistant weeds in GT alfalfa—as well as in crops with which GT alfalfa is rotated—then glyphosate would have to be substituted or complemented in farming by other herbicides. Although the potential for glyphosate-resistant weeds exists in GT alfalfa, it is important to note that there are no studies or data that equivocally demonstrate if GT alfalfa would directly cause the development of glyphosate-resistant weeds, or where glyphosate-resistant weeds would occur in the environment if GT alfalfa were deregulated, or how widespread glyphosate-resistant weeds would be if GT alfalfa were deregulated. As stated previously, although GT alfalfa is likely to result in an increased use of glyphosate, that increased glyphosate use does not immediately or directly result in glyphosate-resistant weeds. Because GT alfalfa is a perennial and the production of GT alfalfa includes mowing, these biological and production characteristics may result in delayed or non-existent glyphosate-resistant weed development and/or delayed or non-existent weed shifts if GT alfalfa is deregulated. Thus, we conclude that the increased use of glyphosate does not guarantee an increase in glyphosate-resistant weeds and even with some potential for an increase in glyphosate-resistance weeds, there is no data to confirm such a potential increase in glyphosate-resistant weeds would amount to a significant effect on the environment.

Currently, APHIS is unable to locate enough quantitative information to predict the impact of GT alfalfa deregulation on organic markets. Any impact, however, will likely be magnified or diminished by the current growth trend in organic markets. If this growth is associated with a growth in demand for non-GE foods, GT alfalfa deregulation may give additional impulse to the demand for organically certified products. If

deregulation increases organic production costs associated with isolation, buffer zones, or relocation, this growth may be slowed.

Deregulation of GT alfalfa could imply losses in exports of conventional alfalfa seed and hay to the main U.S. clients (Saudi Arabia and Japan, for each product respectively). If GE content in animal feed becomes increasingly rejected by international markets, much of this market could be lost. If GE content becomes increasingly accepted, the United States may benefit from the increased competitiveness of GT alfalfa in a market where international competitors are currently gaining ground.

The analysis of the direct and indirect effects of the deregulation of GT alfalfa to human health and safety concludes that under present and expected conditions of glyphosate use, GT alfalfa or the glyphosate herbicide are unlikely to pose a health risk to humans. In terms of herbicide use in conjunction with deregulating GT alfalfa, the cumulative impacts related to the past deregulation of other GT crops increases glyphosate use, and decreases in the use of other, more toxic and persistent herbicides. With more GT crops, there is a greater chance that crops grown for human consumption will be found planted near GT crops, which could result in a greater chance for unintentional glyphosate applications on food crops and a subsequently greater chance for the general public to be exposed. This chance would increase with the deregulation of GT alfalfa. However, glyphosate has been shown to replace more toxic herbicides, so the overall risk to human health, cumulatively, would likely decrease with the deregulation of GT alfalfa. Additionally, glyphosate is currently a widely-used herbicide, and in numerous applications other than agricultural. The additional incremental increased use of glyphosate that would occur with the deregulation of GT alfalfa, along with the current use as described here, would minimally increase exposure to the general public.

Past actions contributing to impacts on surface water pollution include agriculture, industry, resource extraction, urban, suburban, and rural development, and other human activities. Glyphosate will be found in surface water runoff when erosion conditions lead to the loss of surface soil particles. However, deregulation of glyphosate-tolerant alfalfa would likely lead to an increase in conservation tillage and no tillage systems, which could mitigate the increased application of glyphosate by decreasing sedimentation of glyphosate-laden soil particle in surface water runoff (Wiebe and Gollehon, 2006). The quality of surface water may also be improved by conservation tillage, as it reduces erosions and decreases the amount of sediments in rivers and streams.

7. Compliance with Statutes, Executive Orders and Regulations

Executive Order (EO) 12898 (US-NARA, 2008), “Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations,” requires Federal agencies to conduct their programs, policies, and activities that substantially affect human health or the environment in a manner so as not to exclude persons and populations from participation in or benefiting from such programs. It also enforces existing statutes to prevent minority or low-income communities from being subjected to disproportionately high and adverse human health or environmental effects. EO 13045 (US-NARA, 2008), “Protection of Children from Environmental Health Risks and Safety Risks,” acknowledges that children may suffer disproportionately from environmental health and safety risks because of their developmental stage, greater metabolic activity levels, and behavior patterns, as compared to adults. The EO (to the extent permitted by law and consistent with the agency’s mission) required each Federal agency to identify, assess, and address environmental health risks and safety risks that may disproportionately affect children. Each alternative was analyzed with respect to EO 12898 and 13045. Based on the information submitted by the applicant and assessed by APHIS, GT alfalfa lines J101 and J163 are not different than conventional alfalfa and has successfully completed FDA consultation for food and feed use. Therefore, GT alfalfa lines J101 and J163 are not expected to have a disproportionate adverse effect on minorities, low-income populations, or children.

EO 13112 (US-NARA, 2008), “Invasive Species,” states that Federal agencies take action to prevent the introduction of invasive species, to provide for their control, and to minimize the economic, ecological, and human health impacts that invasive species cause. GT alfalfa lines J101 and J163 are very similar in fitness characteristics to other alfalfa varieties currently grown and are not expected to become weedy or invasive (see USDA-APHIS, 2009 for the plant pest risk assessment of GT alfalfa lines J101 and J163).

EO 13186 (US-NARA, 2008), “Responsibilities of Federal Agencies to Protect Migratory Birds,” states that Federal agencies taking actions that have, or are likely to have, a measurable negative effect on migratory bird populations are directed to develop and implement, within 2 years, a Memorandum of Understanding (MOU) with the Fish and Wildlife Service that shall promote the conservation of migratory bird populations. Data submitted by the applicant has shown no difference in compositional and nutritional quality of GT alfalfa lines J101 and J163 compared to conventional alfalfa, apart from the presence of EPSPS. Based on APHIS’ assessment of GT alfalfa lines J101 and J163, it is unlikely that granting nonregulated status to these alfalfa varieties will have a negative effect on migratory bird populations.

a. International Implications

EO 12114 (US-NARA, 2008), “Environmental Effects Abroad of Major Federal Actions,” requires Federal officials to take into consideration any potential environmental effects outside the U.S., its territories, and possessions that result from actions being taken. APHIS has given this due consideration and does not expect a significant environmental impact outside the United States should nonregulated status be granted to GT alfalfa lines J101 and J163. It should be noted that all the considerable, existing national and international regulatory authorities and phytosanitary regimes that currently apply to introductions of new alfalfa cultivars internationally, apply equally to those covered by an APHIS determination of nonregulated status under 7 CFR part 340. Any international traffic of GT alfalfa lines J101 and J163 subsequent to a determination of nonregulated status for the product would be fully subject to national phytosanitary requirements and be in accordance with phytosanitary standards developed under the International Plant Protection Convention (IPPC).

The purpose of the IPPC “is to secure a common and effective action to prevent the spread and introduction of pests of plants and plant products and to promote appropriate measures for their control” (IPPC, 2008); the protection it affords extends to natural flora and plant products and includes both direct and indirect damage by pests, including weeds. The IPPC set a standard for the reciprocal acceptance of phytosanitary certification among the nations that have signed or acceded to the Convention (173 countries as of September 2009). In April 2004, a standard for pest risk analysis (PRA) of living modified organisms (LMOs) was adopted at a meeting of the governing body of the IPPC as a supplement to an existing standard, International Standard for Phytosanitary Measure No. 11 (ISPM-11, Pest Risk Analysis for Quarantine Pests). The standard acknowledges that all LMOs will not present a pest risk and that a determination needs to be made early in the PRA for importation as to whether the LMO poses a potential pest risk resulting from the genetic modification. APHIS’ plant pest risk assessment procedures for genetically engineered organisms are consistent with the guidance developed under the IPPC. In addition, issues that may relate to commercialization and transboundary movement of particular agricultural commodities produced through biotechnology are being addressed in other international forums and through national regulations.

The Cartagena Protocol on Biosafety is a treaty under the United Nations Convention on Biological Diversity (CBD) that established a framework for the safe transboundary movement, with respect to the environment and biodiversity, of LMOs, which includes those modified through biotechnology. The Protocol came into force on September 11, 2003, and

156 countries are Parties to it as of September 30, 2009 (CBD, 2009) . Although the U.S. is not a party to the CBD, and thus not a party to the Cartagena Protocol on Biosafety, U.S. exporters will still need to comply with domestic regulations that importing countries that are Parties to the Protocol have put in place to comply with their obligations. The first intentional transboundary movement of LMOs intended for environmental release (field trials or commercial planting) will require consent from the importing country under an advanced informed agreement (AIA) provision, which includes a requirement for a risk assessment consistent with Annex III of the Protocol, and the required documentation.

LMOs imported for food, feed, or processing (FFP) are exempt from the AIA procedure, and are covered under Article 11 and Annex II of the Protocol. Under Article 11 Parties must post decisions to the Biosafety Clearinghouse database on domestic use of LMOs for FFP that may be subject to transboundary movement. To facilitate compliance with obligations to this protocol, the U.S. Government has developed a Web site that provides the status of all regulatory reviews completed for different uses of bioengineered products (NBII, 2008). These data will be available to the Biosafety Clearinghouse. APHIS continues to work toward harmonization of biosafety and biotechnology consensus documents, guidelines, and regulations, including within the North American Plant Protection Organization (NAPPO), which includes Mexico, Canada, and the U.S., and within the Organization for Economic Cooperation and Development. NAPPO has completed three modules of a standard for the Importation and Release into the Environment of Transgenic Plants in NAPPO Member Countries (NAPPO, 2008). APHIS also participates in the North American Biotechnology Initiative (NABI), a forum for information exchange and cooperation on agricultural biotechnology issues for the U.S., Mexico, and Canada. In addition, bilateral discussions on biotechnology regulatory issues are held regularly with other countries including: Argentina, Brazil, Japan, China, and Korea.

b. Compliance with Clean Water Act and Clean Air Act

This draft environmental impact statement evaluated the changes in alfalfa production due to the unrestricted use of GT alfalfa lines J101 and J163. GT alfalfa is unlikely to lead to the increased production of alfalfa in U.S. agriculture, that is, an increased in the total number of acres planted with alfalfa in the United States. There is no expected change in water use due to the production of GT alfalfa, nor is it expected that air quality will change to do the production of GT alfalfa. If APHIS grants nonregulated status to GT alfalfa, APHIS will be fully compliant with the Clean Water Act and the Clean Air Act.

Appendix B. Public Scoping Comments

Public Scoping Comments

Members of the public were invited to participate in the scoping process for this draft EIS through an announcement of a notice of intent (NOI) to prepare an environmental impact statement (EIS) in connection with making a determination on the status of the Monsanto Company and Forage Genetics International (FGI) alfalfa lines J101 and J163 (Docket Number 2007-0044, 73 FR 1198-1200). In this NOI, APHIS asked for comments, data, and information regarding 18 broad, overlapping issues. APHIS also requested the public to provide suggestions for other issues to be discussed or alternatives to be analyzed in the draft EIS. The comment period for the NOI opened on January 7, 2008. During this comment period, which closed on February 6, 2008, APHIS received 242 comments. Comments were made by interest groups, industry representatives, industry trade organizations, farmers, private individuals, State agency representatives, scientists, agricultural producers, and marketing groups. Full text of the comments received during the open comment period is available online at www.regulations.gov.

APHIS received a number of similar comments from glyphosate-tolerant (GT) alfalfa farmers that identified general issues with growing GT alfalfa, and provided information regarding their specific farming operation. Each of these comments addressed the benefits of using glyphosate instead of other, more toxic herbicides on alfalfa, and that these benefits extended not to just the environment, but also to worker safety. These comments also spoke to the high quality of GT alfalfa, and how this improved quality improves farm revenue. The growers included specific information on the crops grown on their farm, acres of GT alfalfa planted, how many applications and types of other herbicides used prior to GT alfalfa, and documented the number of applications of glyphosate these growers used on their GT alfalfa. These comments concluded with a statement that these growers have neighbors that farm using organic farming practices and/or export their product overseas. According to the comment, these GT alfalfa growers have spoken to their neighbors and these non-GT alfalfa growers do not feel that the use of GT alfalfa is jeopardizing their farming operations, and they strongly support the right to choose which products are used by each farmer on their farm.

Other comments received from the public typically were not in direct response to any of the 18 questions specifically identified in the NOI. Therefore, we grouped the comments into 19 main themes. Below is a summary of the comments received for each theme.

1. Potential of Gene Flow between GT and Non-GT Alfalfa

Association of Official Seed Certifying Agencies (AOSCA) submitted a comment describing the seed certification process for alfalfa. AOSCA further describes this certifying process as a long-standing, voluntary, industry-driven approach to certify seed, including GT alfalfa seed. Seed certifying agencies have developed, and AOSCA has approved, the Alfalfa Seed Production Stewardship Program that uses seed certification standards as its foundations, then augments them with additional considerations intended to promote the stewardship of GE traits. Seed producers, whether intending to contain GE traits in their own seed or acting defensively to keep GE traits out, may contact seed certifying agencies to learn more about the Stewardship Program. AOSCA agencies will work with the producer to identify specific needs they may have and assist in tailoring the program to meet producer or market requirements. Seed certifying agencies will

provide third-party oversight and we are confident that this approach will protect the integrity of the alfalfa seed market.

The California Crop Improvement Association (CCIA), a third party certifier of conventional, GE, and organic seed crops, included comments on their:

- work with the alfalfa seed industry to assure the continued integrity and purity of all crops;
- stewardship plans that include voluntarily set isolation distances that are well in excess of the AOSCA/Federal and State Seed Act minimal requirements;
- pinning map program, which documents the presence, location, and size of fields producing GE seed crops;
- certifying several thousand acres of organic alfalfa hay production;
- reading of National Organic Program (NOP) in that the law does not set a zero tolerance for the unintended low level presence of foreign DNA in an organically produced crop;
- belief that producers of a crop need assurance of the genetic purity of their planting stock, and recommends organic seed producers to use organic seed produced under AOSCA certification; and
- record that CCIA has never had an application from a certified organic producer to produce alfalfa seed under an AOSCA seed certification program.

Several GT alfalfa farmers, conventional farmers, scientists, researchers, and those representing farming interests acknowledge that gene flow is not unique to transgenic plants but a natural process. Commenters acknowledge that gene flow from GT alfalfa can occur; however, it is highly unlikely or is minimized due to:

- the current agronomic practice of harvesting alfalfa prior to flowering, and, therefore, no pollen is produced for gene flow to occur;
- production of hay primarily for the dairy market is typically cut a bug stage, economically the best stage;
- use of boundaries;
- alfalfa that is in production for hay or silage is not allowed to fully mature and set seed—alfalfa is typically harvested months before seed could possibly be set;
- seed-seed and hay-seed are the minority (<2 percent) of potential gene flow situations;
- hay-to-hay is the most common situation; scientific evidence shows this situation is manageable and provides the least opportunity for gene flow;
- best management practices in the cleaning and management of seed harvesting and processing equipment are effective in managing admixtures between GE and conventional alfalfa seed;
- coupled with cultural and rotational practices to manage volunteer seedlings, it is likely that seed-mediated gene flow will be very low;
- feral plants have a large disadvantage over commercial fields as they are not managed; there is a reduced chance of synchronous flowering and a high chance they are destroyed by insect, and thus they seldom produce viable seed. The low relative abundance of pollen and pollinators and the high degree of environmental stress on feral plants relative to those within commercial seed production fields will help reduce the likelihood and commercial importance of seed-to-feral and subsequent feral-to-seed or feral-to-hay gene flow risks to near zero;

- better alfalfa growers who have planted GT Alfalfa and their aggressive cutting schedule do not allow the alfalfa plants or weeds to flower and produce seed; and
- some geographical separation for different marketing strategies would minimize pollen flow.

Some commenters were concerned that non-GT alfalfa will contain GT traits, and thus alfalfa seed growers would not be able to sell non-GT alfalfa seed, or GT traits will always be found in non-GT alfalfa. Other commenters were concerned that this issue was not well studied.

Conventional and organic alfalfa growers commented on specific alfalfa management processes that result in alfalfa seed set in hay fields, which would thus encourage gene flow from GT alfalfa into their fields. Some conventional or organic alfalfa growers, members of the public, and interest groups believe that gene flow between GT and non-GT is a hazard and likely to occur. The reasons below were provided by the commenters:

- Alfalfa is a perennial species that flowers over an extended period and requires pollination by bees.
- A small number of alfalfa seed growers that are concentrated in comparatively small geographic areas.
- GT alfalfa has dormant seed and plants will come up year after year even when there is no new seed source.
- Inclement weather prevents farmers from harvesting, thus allowing additional time for the alfalfa to reach sexual maturity and produce pollen.
- Impacts of flooding on gene flow.
- Research contradicts the assertion that transgene flow produces offspring of lower fitness.
- Weed seeds get by in seed cleaning and virtually all of the serious Midwestern weeds have been introduced through hay or hay seed.
- GE pollen will be released to the natural environment and transported via animals, birds, and insects.
- Equipment such as swathers, balers, hopper boxes, harrow-beds, truck, barns, compressors, and containers will provide a pathway for gene flow.
- There are no feasible measures to protect crops from GT alfalfa gene flow.
- Seed movement is through manure spread on fields.
- Honey bees are present in every seed production area yet are ignored for isolation distances when contracting GT alfalfa seed production except California.
- Alfalfa plants can be very long lived and easily become feral and spread pollen.
- alfalfa hay production with non-tenant landowners and inattentive growers allows alfalfa hay fields to go to excessive bloom.

Interest groups, organic farming interests and members of the public were concerned that organic farmers are considered responsible for protecting organic alfalfa from GT alfalfa gene flow. These commenters wanted to focus the responsibility back to the developer of GT alfalfa, or other farmers who grow GT alfalfa. One commenter believed that regulations protecting non-GE alfalfa seed producers should be enacted before allowing widespread dissemination of GT alfalfa.

Concerning gene flow, interest groups, organic and conventional non-GT alfalfa farmers, and organic farming interests wanted the following assessments conducted or questions answered in the EIS:

- Document the genetic diversity decrease from widespread GT alfalfa seed contamination.
- Effects of GE pollen on conventional alfalfa and alfalfa grass hay fields that are also used to produce alfalfa seed.
- Isolation distance requirements to prevent contamination of non-GT alfalfa fields.
- To what extent can organic or conventional alfalfa farmers prevent their crops from being commingled with unwanted, unintended, or unexpected GT alfalfa.
- How will seed be kept separate so that farmers can be assured they are not getting GT alfalfa seed.
- An assessment of gene transfer and the extent to which deregulation of GT alfalfa will affect hybridization between cultivated and feral alfalfa.
- At what gene flow level does APHIS consider the use of mitigation measures such as stewardship practices as a failure due to increasing levels of GT genetic contamination.
- An interest group wanted APHIS to avoid relying on external gene flow scientists who have been paid by Monsanto and FGI to avoid the appearance of bias and unethical research motives.
- Independent research analyzing how long it takes for hard seed to break down in the soil.
- Could a 'marker' be included in GT alfalfa that would have permitted GT alfalfa to have been cleaned out of the conventional seed by special seed cleaning equipment.
- Transfer of GT seed residues from seed cleaning facilities into conventional seed that is subsequently cleaned at the same facility.
- The feasibility of thoroughly removing GT alfalfa seed residues from farm equipment and seed cleaning facilities, given the size of alfalfa seed.
- Assess establishment of volunteer GT alfalfa in fields rotated from GT alfalfa seed or forage production to conventional alfalfa seed or forage production.
- Assess the quantity of alfalfa seed left on the ground after harvest, and the viability of such seed in various rotation scenarios.
- If the GT alfalfa stand is plowed under, what is the viability of unharvested and hard seed after plowing.
- Further study of the soil or other environmental factors fostering increased hard seed prevalence in GT alfalfa.
- APHIS should commission testing of a representative range of conventional alfalfa seed varieties in various alfalfa-producing regions to determine the extent of GT trait presence, and determine the route and cause of contamination wherever possible.
- An assessment of the route and cause of unwanted GE traits in other crops.
- Examine other bees that have not yet been addressed in gene flow studies.
- How long is alfalfa pollen proven viable to zero viability.

2. Difference in Weediness Traits between GT and non-GT Alfalfa

Several commenters felt strongly that the presence of GT alfalfa in agriculture is not likely to increase the weediness traits of sexually compatible and/or feral populations of alfalfa since common agricultural practice for alfalfa is to harvest prior to flowering, and, therefore, the chance of gene flow occurring and creating glyphosate-resistant alfalfa weeds is unlikely.

One commenter was concerned that genetically-engineered (GE) plants will become invasive species, and because the GE versions of non-GE plants look similar, it will be difficult to determine which version is invasive. This commenter advocated the precautionary approach. An interest group believes that gene flow from GT alfalfa to feral alfalfa may increase its weediness potential. Interest groups also called for the following issues related to weediness to be analyzed in the EIS:

- weediness traits evolving in organic alfalfa versus GT alfalfa.
- differences in weediness traits between organic and conventional alfalfa.
- the potential impacts of GT alfalfa introduction on agricultural lands other than alfalfa because it has been reported that alfalfa can be a weed problem in sugar beets, onions, vegetable seeds, orchards, vineyards and in rangeland plants grown for seed.
- according to an interest group, because a tendency to dormancy (i.e. hard seed) correlates with the weediness potential of a crop, the EIS should include a follow up on Monsanto's finding of a two to fourfold increase in the percentage of hard seed in GT alfalfa vs. controls.

Another commenter believed that, although introduced to North America hundreds of years ago, alfalfa is not a weed because alfalfa—

- is difficult to establish;
- does not tolerate unfertile soils, soils that are too acid or too alkaline or soils that are poorly drained; and
- must be nodulated with the proper strain of *Rhizobium*, which is seldom found off-farm.

3. Weed Management Practices in Alfalfa Production

Members of the public, some organic and conventional farmers, and interest groups stated that control of weeds in alfalfa is best done through:

- crop rotations;
- companion crops (oats or grass mixtures were suggested);
- stubble with no-till agriculture;
- vinegar;
- healthy stands of alfalfa;
- light use of glyphosate early in the growing season and between cuttings;
- fertile soil and proper soil pH;
- non-glyphosate herbicides;
- more phosphorus in soil; and
- adequate brix levels.

Interest groups also commented about:

- the assessment of voluntary weed resistance management or stewardship;
- use of mandatory herbicide resistant weed management programs administered by APHIS;
- an assessment of the success or failure of past efforts to limit the spread of resistant weeds through voluntary weed management or stewardship programs;
- why the great majority of alfalfa hay acreage is not treated with any herbicides

- an assessment of weed control should include “best management practices” in conventional and organic alfalfa production; and
- why is herbicide used on the minority of alfalfa hay acreage. One interest group stated that deficient soil fertility, unfavorable soil pH, overly prolonging the life of thinning alfalfa stands, and attacks by disease or nematodes are factors that may make alfalfa more susceptible to weed invasions.

GT alfalfa growers felt that glyphosate herbicide is less toxic, both to humans and the environment, than other herbicides used to control weeds in alfalfa, and needs to be applied less frequently than other, more harmful chemical herbicides. Alfalfa farmers growing GT alfalfa additionally commented on:

- Their compliance with the stewardship requirements for GT alfalfa grown for hay or seed
 - Some farmers mentioned the amount of oversight on the stewardship requirements
 - A seed production manager commented that the GT alfalfa growers he interacted with were good stewards of the technology and followed the strict guidelines imposed by Monsanto and FGI.
- Lack of weed problems related to GT or feral alfalfa in fields or road ways
- Using glyphosate with GT alfalfa allowed them to control weeds that were not easily controlled in conventional alfalfa production, particularly in areas of flood irrigation. A weed scientist notes that growers who have problems with perennial weeds cannot use conventional herbicides to control these weeds in alfalfa. The commenters felt that the use of glyphosate in these areas provides an opportunity to economically produce alfalfa and control perennial weeds. Some of the weeds mentioned include:

▪ Russian knapweed	▪ Chinese lettuce
▪ Tall white top	▪ Morning glory
▪ Field bindweed	▪ Canada thistle
▪ Jenny	
- Weed control using glyphosate allows growers an affordable and economical means of reducing weed pressure in alfalfa
- Some farmers farm in sandy soils and stated that no herbicides were available for acceptable weed control until this technology became available
- A certified crop advisor stated that prior to glyphosate, three different chemicals had to be used to control weeds that persisted in soil for far greater periods and had detrimental effects on alfalfa yields and quality
- The majority of commenters that grow GT alfalfa (and did not submit a form letter as discussed above), and some commenters representing conventional farming interests believe that GT alfalfa is the best option to control weeds in alfalfa stands, stating broadly that less chemical is required than growing conventional varieties
- GT alfalfa farmers and other commenters representing farming interests state that GT alfalfa is a potential solution to the various weed infestations in areas where alfalfa is grown and is preferable to other traditional herbicides as it does not stunt the growth of alfalfa stands
- A commenter from academia suggested that APHIS not only examine the impacts of chemical and non-chemical weed control practices, but also the impact of failing to control weeds by any method

- Another commenter stated that, like soybean, alfalfa already has some glyphosate tolerance to begin with, and as a consequence, glyphosate may not be the best control choice in a worst-case scenario of feral alfalfa in a natural area.
- A commenter suggested that the greatest problem with neighbors is that they moved “to the country” because “it’s so beautiful”, but they do not have the equipment and do not take time to take care of their weeds and help keep it beautiful. They let the weeds go to seed, then they break off and roll across our fields when it is windy and those weeds seed our alfalfa fields.

4. Glyphosate-Resistant Weeds

Some commenters discussed the historical aspects of herbicide resistance in weeds, stating that with each new chemical, there have always been shifts in weed composition and weeds which acquire resistance, and that this is an issue faced with all herbicides, not just glyphosate.

Some commenters suggested ways to prevent weed shifts or resistant weeds, including:

- rotating herbicides (some commenters believe that rotating pesticides has become more of a standard practice due to the understanding of resistance development)
- stacked herbicide resistance traits will add to the sustainability of herbicide use

Some GT alfalfa farmers stated that farmers recognize the potential of herbicide-resistant weeds, and use each herbicide only when necessary at labeled legal rates to control specific target weeds, and farmers would use the “best practices” approach in raising GT alfalfa to minimize glyphosate-resistance weed development.

A weed scientist believes that there is a low risk of glyphosate-resistant weeds developing in GT alfalfa due to glyphosate use during the year of stand establishment. The comment states that glyphosate does not injure the alfalfa and can be utilized as soon as weeds emerge, reducing weed competition with alfalfa and improves alfalfa stand establishment. The comment continues by stating that following the first harvest, alfalfa takes over weed management if a dense stand is achieved, thus, applying additional herbicide is not necessary until several years later when the alfalfa stand begins to thin. The comment concludes stating that with GT alfalfa the majority of growers will not apply multiple treatments of glyphosate and therefore selection for resistant weeds is of low risk. Other GT alfalfa farmers submitted comments that echoed the idea that GT alfalfa and the use of glyphosate would not result in glyphosate-resistant weeds because of the management practices and biology of alfalfa.

Some conventional and organic alfalfa farmers, along with members of the public and interest groups were concerned about glyphosate use on GT alfalfa leading to the development of glyphosate-resistant weeds. Some of these comments also voiced concern that different and expensive herbicides would eventually be required to control new weeds, and believed that these different and more potent herbicides pose risks to the environment and wildlife.

Some commenters were concerned about some poisonous weeds becoming more prevalent because of the use of glyphosate, including nightshade and field horsetail. A conventional seed grower in Montana believes that there is only a three year window before the weeds begin

building resistance to glyphosate. A conventional alfalfa grower was concerned about what might happen with the alfalfa plants that glyphosate cannot kill, and how burdensome the removal will be to the public.

Interest groups, organic and conventional growers, and members of the public described assessments they wished to see in the EIS, including:

- the effect of widespread use of GT crops;
- the impacts of glyphosate-resistant weeds due to GT alfalfa in combination with the:
 - growing adoption of other GT crops;
 - recent introduction of GT crops that allow for increased use of and expanded application window for glyphosate
 - likely introduction in the near future of GT crops
- rotation between different GT crops;
- the potential for spread of glyphosate-resistant weeds via resistant weed seed present in alfalfa seed, and how this might be exacerbated by introduction of GT alfalfa;
- an assessment that encompasses other weed species that have biotypes with confirmed glyphosate-resistance in other countries; and
- the cumulative impacts on weed control costs of the introduction of GT alfalfa against the backdrop of currently grown GT crops, for growers of alfalfa and other crops.

5. Potential Impacts of GT Alfalfa or Glyphosate on Wildlife

A state farm bureau stated that the NOI question regarding endangered species and critical habitat only considers the use of glyphosate on species or habitat; it does not consider that farmers actually have fewer passes in the field due to the use of GT alfalfa, which can have a beneficial impact on species and their habitat.

An alfalfa farmer states that additionally, there is no evidence that glyphosate will harm any threatened or endangered species or organisms that are beneficial to agriculture.

A commenter states that in the short time that we were allowed to plant GT alfalfa we have, in our pheasant hunting operation, been able to establish an alfalfa stand on parts of our farm that would not have let us otherwise as weeds and grasses would have smothered out the alfalfa plants. Alfalfa is second to none to be used for nesting habitat and is a great source of food for deer and other wildlife.

Organic farmers, conventional farmers, interest groups and members of the public requested the following information regarding the relationship between GT alfalfa and wildlife discussed in the EIS:

- the potential interaction of increasing levels of glyphosate in the environment on other animals and creatures, such as frogs and other sensitive animals;
- what happens to deer that eat GT alfalfa;
- the impact of insecticides and herbicides on the biodiversity and productivity of aquatic communities;

- what are the effects on insect breeding and on aerial spraying of insects should GT alfalfa be permitted to be used generally, and what are the health effects of increased spraying of toxic substances and poisons; and
- what range of organic chemical impurities and inorganic chemical impurities from the manufacturing process are detectable in glyphosate that may cause or contribute to negative impacts on threatened or endangered species, insects, or wildlife?

6. Pollinator Concerns

Beekeepers, conventional and organic alfalfa growers, members of the public and interest groups were concerned about the relationship between GT alfalfa and pollinators. Issues included:

- management practices for GT alfalfa prohibit bee colonies near GT alfalfa fields, which may result in adverse effect on honey bees, the beekeepers, and honey production;
- link between colony collapse disorder (CCD) and GE crops ;
- effects of GT alfalfa pollen on bees;
- the use of glyphosate will eliminate any pollinator forage habitat in agriculture; and
- effects of GT alfalfa on pollinators and insects was not well studied

One GT alfalfa grower states he raises leafcutter bees for alfalfa seed pollination, and is not afraid to exposed the bees to this crop.

One farm growing both conventional and GT alfalfa has had a long term relationship with a local beekeeper and has had bee colonies on the land for many years. The commenter states that we are trying to produce high quality alfalfa, we cut before the plant goes into bloom. The commenter notes that the beekeeper feels that GT alfalfa poses no threat to his bees and the beekeeper has seen no change in his colonies since we have planted the fields of GT alfalfa.

Interest groups, beekeeping interests, conventional alfalfa and organic alfalfa farmers wanted the following pollinator-related issues assessed in the EIS:

- establish whether there is any reduction in the nutritional value of GE alfalfa as relates to honeybees;
- what is the impact of variation in the nutritional value of pollen on the environment;
- show the economic impact of crowding out honey and pollinator industry for alfalfa seed production;
- test for safety of GE pollen in honey;
- will honey made by bees foraging on GE alfalfa continue to be readily accepted by consumers who are leery of all GE products;
- can honey obtained from GT alfalfa be sold as organic;
- does glyphosate use in GT alfalfa fields have negative impacts on bee populations and colonies;
- what are the effects of widespread use of GT alfalfa on insects which pollinate agricultural crops;
- what range of organic and inorganic chemical impurities are detectable in glyphosate that may cause or contribute to impacts on bee populations and colonies; and
- do we have scientific evidence showing that CCD is not caused from bees foraging on GT Alfalfa.

One scientist commented on the effects of GE crops CCD. The comment states that although the suggestion has been made that GE crops contribute to CCD, the Colony Collapse Disorder Action plan developed by the CCD Steering Committee and presented in June 2007 found that there is no evidence that the use of GE crops has contributed to CCD. The comment states that evidence against GE crops contributing to CCD include the fact that large bee die-offs have also occurred in Europe where GE crops are not widely grown and extensive laboratory and field testing has indicated a lack of acute and sub-lethal effects on bees exposed to GE-pollen.

7. Effects of Glyphosate in Agriculture

Some commenters pointed out the glyphosate is a salt-based herbicide and goes on to state that weeds like salt and it seems counterintuitive to use a salt-based herbicide to control populations of weeds that prefer salts.

Related to glyphosate use, interest groups, conventional and organic growers, members of the public, and organic farming interests wanted the following assessments conducted or questions answered in the EIS:

- What levels of glyphosate can be expected in the harvested alfalfa crop, and what is the animal exposure to glyphosate residuals in GT alfalfa
- The effect on 'sustainable' environment if glyphosate is widely used on GT alfalfa
- How long does glyphosate take to break down
- Assess potential adverse impacts from application of glyphosate to GT alfalfa with various glyphosate application methods
- Include projections of the amount of glyphosate applied to RR alfalfa in the future
- Assess the impacts on threatened or endangered species of glyphosate use associated with GT alfalfa on plants growing in or near alfalfa fields
- With the extensive use and frequent applications of glyphosate, what period of time will be required to dissipate glyphosate from these lower soil profiles, or prevent the leaching of water soluble glyphosate into ground water
- Are there data gaps in ground and surface water monitoring programs to adequately assess the impacts of glyphosate residues? If so how should these data gaps be addressed?
- How many states with glyphosate in agricultural use routinely conduct water testing that includes testing for the herbicide glyphosate and all known glyphosate residues present or have a potential to be present in the ground and surface water
- How frequently is glyphosate contamination and all known impurities like 1,4-dioxane detected in the ground and surface water monitoring programs in the United States
- How many drinking water alerts been issued by states or municipalities due to glyphosate contamination and glyphosate-related contaminants in the ground and surface water conduct testing
- How many public or private drinking water wells in the United States have been contaminated or permanently closed by glyphosate contamination
- Has Monsanto cooperated with local, state or federal agencies in cleaning up drinking water wells contaminated by glyphosate contamination
- What remediation steps were taken and what was the cost to cleanup drinking water wells in the United States contaminated by glyphosate contamination

- Will Monsanto pay any portion of the economic cost of remediation that may have to be made to cleanup drinking water wells in the United States contaminated by glyphosate contamination
- How much has Monsanto paid to date in cleanup costs for cleanup drinking water wells in the United States contaminated by glyphosate contamination? If Monsanto has not paid, where will the cleanup costs come from?
- Has the U.S. Environmental Protection Agency paid for any of the glyphosate contaminated drinking water cleanup costs in the United States for past contamination
- Has Monsanto or any farmers been sued by private individuals or governmental entities for allegations of glyphosate contamination in drinking water
- What is the cost of providing clean drinking water for residents who have had their drinking water contaminated by glyphosate
- Has Monsanto developed or funded a filtration process for remediating glyphosate from contaminated water?
- How much would it cost for a family with contaminated drinking water to filter 100% of their water adequately to remove glyphosate residues
- Will the U.S., state or local governments pay for any costs for a family for 10 years with contaminated drinking water to filter 100% of their water adequately to remove glyphosate residues
- Comprehensively review and consider all possible biological effects of glyphosate exposure
- Conduct a comprehensive literature review of medical and related studies investigating links between glyphosate and non-Hodgkin's lymphoma
- What is the minimum detectability limit that is performed, how many sample are collected, and what analytical chemical methods to test batches for the presence of organic or inorganic chemical impurities including 1,4-dioxane
- What purification and separation technologies are used, and what is the efficiency, to attempt to remove organic chemical impurities or other impurities from glyphosate production batches including 1,4-dioxane
- Will APHIS investigate and review all of this information in the EIS that glyphosate contains detectable concentrations of 1,4-dioxane evidently as impurities in the polyoxyethylene alkylamine inert ingredients?

A retired academic provided his concerns about the use of glyphosate. He believes that glyphosate:

- Increases disease, reduces nutritional quality, and enhances environmental degradation
- Increases the population of *Fusarium* and other soilborne pathogens
- Extends host range of pathogens
- Is released into the soil environment through plant root exudates where it is toxic to many beneficial soil microorganisms
- Persistence in some soils from common "weed burn down" applications is well documented and countries have a recommended delay period on the label before planting a susceptible crop
- Residual levels inhibit root uptake of the essential micronutrient manganese, and greatly restrict translocation of copper, iron, manganese, and zinc

- Resistant genes reduces the uptake or efficiency of Cu, Fe, Mn, and Zn that are essential trace mineral nutrients for plants, animals, and humans

A foreign citizen was concerned that glyphosate tests are done on the active ingredient only and states that the herbicide formulation has been found by some researchers to be more damaging than the active ingredient alone.

An interest group is concerned about the use of 1,4 dioxane as an impurity in surfactants in glyphosate formulations, the use of glyphosate on its effects on human health, animals, and the environment, and supplied references to studies.

An interest group notes that EPA established a tolerance of 0.5 ppm glyphosate on alfalfa seed to facilitate introduction of GT alfalfa; there were unaware of if glyphosate residues were permitted on alfalfa seed prior to this tolerance decision, and unaware if any tolerance has been established for glyphosate residues on alfalfa hay.

GT alfalfa growers were concerned about the use of other herbicides on alfalfa besides glyphosate, because they felt that glyphosate is safer, both for the plant and for the environment and other herbicides are more expensive and have little effect on weeds. They felt that GT alfalfa will lead to the reduction of more toxic herbicides being used to control weeds in alfalfa. Further, they felt that since glyphosate is so safe to use, harvest restrictions and grazing restriction intervals are all but eliminated.

8. Potential Economic and Social Impacts of GT Alfalfa

Impacts due to the Court-ordered injunction that halted new plantings of GT alfalfa

A regional bank is concerned because as a lending institution commitments are made to producers with the expectation that what they do provides a financial benefit to themselves, contributes to the economy of the region, provides employment, is a sound agricultural practice, and is of course legal. The comment continues: while issues are being explored that may change the decision in time, the fact remains that producers have already invested their capital, borrowed capital and structured their operation around the production of this crop. Because of the long stand life of an alfalfa crop, the negative financial impact of this order on the producer is a reality. In addition, what appears to be ignored is the fact that neither traditional (organic) alfalfa crop producers nor GT alfalfa crop producers benefit from any cross contamination of either crop from a marketing perspective. One can argue the issues surrounding genetic engineering and the environment all day long, but at the end of the day the court has determined with what appears to be a limited amount of information that a business engaged in the legal production of a crop should simply immediately cease to exist.

One alfalfa grower emphasized that farming is a very low margin business. The only way a farmer can stay in business is to be able to grow the best quality and the highest quantity of crops as possible with the most cost effective practices available. The comment states that using GT alfalfa is the only way to grow certifiable, weed-free hay that can be taken into the National Forest without spreading weed seeds as well as alfalfa seeds. Half of the commenter's farm is on hold, waiting for these proceedings to be completed to finish planting with GT alfalfa. The

commenter wishes to not continue our old practices to control the weeds as they do not work effectively on our farm even with spending huge amounts of money on fuel and chemicals and being in the fields 24-7. We believe we should have the right to make a choice as to the kind of alfalfa we plant.

Growers were concerned about the income loss from not being able to plant GT alfalfa seed, including the cost of controlling weeds in conventional seed as compared to GT alfalfa seed, loss of yield, the extra expense in labor of spraying and the cost of running the sprayers, the extra expense in cleaning out the weed seed, and the cost of freight in trucking dirtier seed.

One supply and marketing cooperative found that the regulation of GT alfalfa caused significant losses for alfalfa growers in the Midwest. The comment continues: the release of the first GT varieties drew the immediate attention of the farmer owners of our cooperative. All available GT alfalfa was sold in 2005 and 2006. The level of grower satisfaction surpassed expectations and the cooperative received no complaints about the product. This same commenter referenced the Iowa State University Hay Market News on January 7, 2008: the highest prices were paid for Supreme quality alfalfa hay and as the quality declined the price declined. The commenter noted that no where in this hay market report is there a premium for organic or conventional hay nor is there a discount on GT hay.

One alfalfa grower stated that the re-regulation of GT alfalfa have created a real problem for our farm plan for the next four years. The comment continues: as you know, this perennial crop is planted and grown for four - six years before rotation. After the decision to regulate GT alfalfa this summer, we had to go back in time and plant 900 acres of conventional seed for alfalfa hay production which was scheduled for GT alfalfa. In our area we have a real problem with noxious weeds which can not be transported across state lines in California where our market is located. In the past, we have had trucks rejected at state line due to noxious weeds. GT alfalfa has been the answer to this problem for us, not one rejected load; our quality and production has increased with GT alfalfa.

One commenter felt that the injunction preventing new plantings of GT alfalfa is costing the American farmer millions in lost revenue due the enhanced productivity of this product. In turn the economic impact to the communities in which these farms exist are suffering as well. Other commenters felt similarly, in that the injunction will result in financial harm to growers and seed dealers.

An alfalfa grower feels that this injunction is a crock, nothing more than a fight for a dollar, and guesses this bunch would have us ban tractors and start farming with mules and horses again.

One commenter was concerned that the inability to access GT alfalfa will put us back into the downward spiral of lower quality hay we were in before. The commenter states that in a very short time it will take from us our ability to produce premium grade Race Horse Timothy; it is the only crop that keeps our farms from becoming the subdivisions of another bedroom community to Seattle.

Compensation issues for growers of non-GT alfalfa

Commenters who either grow crops using organic methods or prefer to consume foods that have been grown using organic methods are concerned about who will compensate them for the loss of organic products or the increased cost consumers must bear to continue enjoying organic foods, and who will compensate conventional and organic producers for their losses and/or increased costs.

Alfalfa seed processors are concerned about their liability if they process alfalfa seed that inadvertently contains the GT trait.

An organic association wanted benchmarks developed that establish distinct mileposts and guidelines for compensation of organic farmers and the manufacturers of organic products should their welfare and livelihood be damaged by GE contamination.

An organic association wants a system developed to contain and halt the spread of such contamination should it occur as well as the establishment of remedial actions to address any contamination.

An alfalfa seed producer wanted to know the economic impact of making FGI responsible for the stewardship of their patented genetics of the GT alfalfa.

One commenter stated that GT alfalfa should only be allowed if a farmer who is not growing GE crops is allowed to sue the manufacturer if the GE crop contaminates his crop by whatever means.

One commenter stated that creator of GT alfalfa should be responsible for all adverse effects caused by adventitious presence. Many organic growers and interest groups feel that the non-GE seed grower should not be responsible for keeping GE pollen out of his/her field. That responsibility should fall upon the owner of the technology contained in said GE pollen.

A law professor states that organic growers who sign contracts promising that their alfalfa will be completely free of all detectable traces of GT-alfalfa have voluntarily contracted to meet product specification standards that are above and beyond those required by National Organic Program standards. The commenter continues by stating that organic growers who voluntarily sign contracts setting forth such product specification have obligated themselves to meet that product specification; they have no legal claim against anyone else if they then fail to satisfy the voluntarily accepted product specifications in their own contracts.

Other economic and social impacts

A sustainable agriculture group believes that when cross contamination does occur, it will result in the loss of organic certification.

A law professor states that so long as organic alfalfa growers do not intentionally use GT-alfalfa and take reasonable measures to avoid use and or contact, these organic growers do not lose organic status for their farmland or their organic alfalfa under National Organic Program (NOP) standards. NOP regulations and their accompanying comments make clear that organic farmers are not at risk of losing organic certification for the farm or the product so long as the organic

grower complies with the applicable organic grower plan.

One non-GT farmer feels that if a producer within pollen-drift range plants GT alfalfa my rights to grow conventional hay, seed, will be violated.

One commenter felt that it was very important to hear from organic hay producers and conventional hay producers about how the deregulation of this trait might affect their farms.

One commenter believed that organic farmers have the only true concern seen. The commenter believes that the economic impact to these farms can and should be documented, however, the same impact study should be one done on all the farms that produce alfalfa. The fractional acres of organic farms in the United States as a whole would suffer much less economic impact than if this product did not make it into the hands of all farmers. These farms and the towns they reside are not being supported by the additional revenues that will come.

An conventional alfalfa hay and seed grower states that to reduce fuel costs and unnecessary additional harvesting expenses, his stands grow into bloom, which is conducive for conventional alfalfa seed production on his hay ground. The commenter then states that this seed may be sold as common, vernal. Etc., and the source of income is important to growers such as myself.

Interest groups, organic growers, some conventional growers, and organic farming interests were concerned about various economic and social ramifications of GT alfalfa, and requests the following issues be addressed in the EIS:

- How will hay growers keep GE alfalfa separate from conventional alfalfa
- Who will pay for testing conventional hay to make sure it is GE free
- When the GE alfalfa escapes cultivation and become a weed along road sides, and in waste ground will it be possible to remove all contamination in the future? Who will be financially responsible for cleanup if in the future there is a problem?
- Can low-level presence of GT alfalfa can be marketed as “conventional” or “organic”
- What is the cost of testing to satisfy customers who prefer non-GT alfalfa, at whatever no-tolerance or low-tolerance levels desired
- Who has liability or reestablishment of productivity and beneficial micro flora, detoxifying residual glyphosate in the environment and subsequent non-target effects, and removal of the gene from non-target alfalfa
- The costs of implementing effective measures to prevent (not just mitigate) transfer of the GT trait to conventional, organic and feral alfalfa
- Survey domestic and foreign alfalfa purchasers to determine their rank-order preference for organic alfalfa, conventional alfalfa, and GT alfalfa
- Survey prices offered for each type of alfalfa
- Assess the loss of premiums for organic alfalfa resulting from the presence of the GT trait in non-GT alfalfa supplies
- Assess the financial viability of organic alfalfa or GE-free alfalfa cultivation with reduced premiums
- Assess opportunity costs from loss of the option to cultivate GE-free conventional and organic alfalfa occasioned by the introduction of GT alfalfa

- An assessment of the likely shift of organic/GE-free conventional alfalfa seed and forage production to countries whose farmers can guarantee GE-free supplies.
- Assess costs borne by conventional/organic farmers in attempting to avoid transgenic contamination, including but not limited to: purchase or lease of land to create larger buffers separating them from GT alfalfa producers; and any other changes in cultivation practices (e.g. temporal isolation) forced on conventional/organic growers to avoid transgenic contamination
- Formulate and analyze various mechanisms by which GT alfalfa growers and/or companies selling GT alfalfa can be required to compensate organic and conventional alfalfa farmers for loss of markets or loss of income (i.e. premiums) from transgenic contamination of alfalfa supplies for markets that reject such supplies due to presence of GE content
- Formulate and analyze various mechanisms by which GT alfalfa growers and GT alfalfa seed suppliers can be required to compensate organic and conventional growers for their increased expenses associated with GE content testing and attempts to avoid transgenic contamination of their alfalfa
- Assess the long-term consequences of GT alfalfa introduction on the viability of private and any remaining public-sector alfalfa breeding programs in the U.S.
- What are the costs of breeding out an inadvertently-introduced GT alfalfa trait?
- What are the financial consequences of contamination for United States breeders of conventional alfalfa?
- What losses may be expected from a shift of alfalfa breeding programs to other countries where transgenic contamination of experimental alfalfa varieties can be avoided?
- How much is 'low-level' presence of GT alfalfa in non-GT alfalfa?
- What is the negative economic impact to retailers and wholesalers if they lose sales of organic alfalfa sprouts and other organic alfalfa food products because the organic alfalfa food items are contaminated with GT alfalfa ingredients and little or no organic alfalfa is available?
- What is the negative economic impact to retailers and wholesalers if they lose sales of organic alfalfa sprouts and organic alfalfa food products because consumers are concerned about the threat of contamination by GT alfalfa ingredients?
- What is the negative economic impact to organic and conventional alfalfa growers if they lose sales of organic (and conventional) alfalfa sprouts and organic alfalfa food products because the organic (and conventional) alfalfa items are contaminated with GT alfalfa ingredients and no organic alfalfa is available?
- What is the negative economic impact to organic and conventional alfalfa growers if they lose sales of organic (and conventional) alfalfa sprouts and organic alfalfa food products because organic food retailer and wholesalers refuse to buy these food items due to their concerns about the threat of contamination by GT alfalfa ingredients?
- What is the negative economic impact to organic and conventional alfalfa growers if they lose sales of organic (and conventional) alfalfa sprouts and organic alfalfa food products because consumers refuse to buy these food items due to their concerns about the threat of contamination by GT alfalfa ingredients?
- What are the range of economic costs to organic or conventional alfalfa seed growers of having to conduct annual DNA tests of their alfalfa seeds for the presence of GT gene contamination?

- What is the range of economic costs to organic or conventional alfalfa farmers/growers of having to conduct annual DNA tests of their alfalfa seeds and alfalfa crops for the presence of GT gene contamination?
- What extent of alfalfa seed and alfalfa crop DNA testing will be needed to be performed each year by organic and conventional alfalfa farmers to sample their alfalfa seeds and alfalfa crops for the presence of GT gene contamination?
- What is the range of economic costs passed on to consumers who consume products derived from organic or conventional alfalfa if the farmers have to conduct annual DNA tests of their alfalfa seeds and alfalfa crops for the presence of GT gene contamination?
- What is the range of economic costs to organic or conventional food retail and wholesale companies of having to conduct annual DNA tests of their alfalfa seeds and alfalfa crops for the presence of GT gene contamination?
- What is the range of economic costs to organic or conventional alfalfa farmers if they had to label their GT contaminated alfalfa seeds and alfalfa crops when the presence of GT gene contamination is detectable?
- What are the economic costs to food retailers or wholesalers if they had to label their GT contaminated alfalfa seed products and alfalfa food items when the presence of GT gene contamination is detectable?
- What would be the costs borne by a company such as Monsanto to pay for GT testing if their GT alfalfa crop contaminates neighboring non-GT alfalfa crops?
- Examine historical data to evaluate trends in selling prices for conventional and organic alfalfa, in particular premiums offered for organic alfalfa. Based on these data and current trends, APHIS should project the selling price and premiums for organic alfalfa for at least one decade into the future.
- APHIS' analysis should accept the need to preserve the option of farmers to grow and market organic alfalfa free of unintended transgenic content in all alfalfa-growing areas, now and in the future.
- How will GT alfalfa affect the cattle market value?

One commenter believes that the need for establishing a GE Free or conventional production zone is to be able to continue to sell alfalfa seed to the organic seed markets with the lowest possible occurrence of adventitious presence. The commenter states that seed from this production area has been sent for the organic hay market for seed planting and the one thing that is requested by the organic growers and the organic certifier is a letter of verification of production of conventional seed production.

Seed producers, cleaners, and hay producers will all lose if common seed, which is less expensive, becomes contaminated and eventually eliminated.

One commenter believed that organic and non-organic producers have co-operated amiably to mitigate the potential for contamination.

From an alfalfa seed grower: alfalfa growers will have a difficult time competing with corn growers from a profitability standpoint if we are not allowed to utilize the genetic advances already available to corn growers. This schism will be accentuated as new genetically modified

traits become available for corn and future advances in alfalfa are squelched as a result of this action against alfalfa.

An alfalfa grower stated that our main goal is to supply high quality hay to our dairy customers. The commenter continues: of the 27,000 tons we produced in 2007, approximately 20% had enough grass to warrant a reduction in price. These reductions ranged from \$10-15 per ton and we lost approximately \$50,000 as a result of the deductions for grass. The commenter stated that grass is a prevalent problem in our area and dairymen closely scrutinize the bales and expect a deduction for any grass that is present: none of our GT fields had any grass present and we would expect this to be the case for the entire life of these stands.

An alfalfa producer states that GT alfalfa is essential to stay profitable in the alfalfa business, and to provide a quality product for consumers.

An alfalfa farmer believes that where sandy soils prevail organic farming is an insult; we do not desire to return to the dirty 30's, which is what organics would do. In the commenter's opinion, "organic farming" is only a smart marketing tool, and really is a method to sell sub-par quality products to an uninformed public at a premium price.

A GT alfalfa grower feels that GT alfalfa fields are much cleaner, produced more alfalfa, use less herbicide than the conventional alfalfa fields and less fuel is used in GT alfalfa fields because of the fewer trips across the field for spraying and raking the hay.

A group of academic pointed out that the primary commodity for alfalfa is forage hay and not seed. This group believes that there is no documented certified organic seed in the United States, although there is likely a small proportion grown organically. The commenters state that there is no doubt that the organic market will grow with demand from organic dairies, but it will likely remain the minority of total production, even if it grew 10 fold.

9. Potential Trade Impacts of GT Alfalfa

One commenter believes that because of the potential for disruption to the seed trade environment, GT alfalfa seed production needs government regulation and oversight.

A conventional alfalfa seed farmer, who has grown seed for Argentina, Saudi Arabia, France and Turkey, is cognizant of pollinators and the distance they travel and, because of those factors, does not raise any GT alfalfa seed in our area of over 8,000 acres. The commenter states he is aware of both the sensitivity of some markets of GE traits and the great benefits that genetic engineering has brought to American agriculture. The commenter believes that the Best Management Practices formulated by NAFA can lead to a coexistence between seed grown for organic agriculture, export markets, and GT markets.

A conventional seed grower group believes a GE Free or conventional production zone is needed to export conventional alfalfa, because alfalfa hay growers in the Pacific Northwest who export their hay to foreign countries want the reassurance that the seed that is planted is conventionally

grown so they can assure GE-free hay. This group states that they recognize that foreign governments have accepted GT alfalfa, but not all end-use buyers.

A regional hay grower group supports the advancement of technology and science to keep agriculture viable and productive, however they do not want GT alfalfa released until market acceptability and approval in all markets, assurances of public food safety, and proof that use of GT alfalfa will not contribute to the development of glyphosate resistant weeds rendering glyphosate useless for future use has been assured.

A hay exporter states although the Japanese government has approved the sale of GT alfalfa, Japan's marketplace (importers, agricultural cooperatives and dairymen) does not want to buy GT alfalfa.

An GT alfalfa grower states that his primary crop is Timothy hay, which he exports to Japan, but blue grass is beginning to infest fields. The blue grass infestation then reduces premium grade Race Horse Timothy to lower grade cattle hay. We have tried many types of crop rotations including regular alfalfa, and GT alfalfa is the first crop to show the potential solution to this blue grass problem. The commenter continues: while there seems to be a lot of talk about non-acceptance of GT alfalfa, we were able to export our crop last year to both Korea and Japan; both customers knew it was GT alfalfa and we have Japanese and Korean buyers standing in line to buy this product at a premium price.

Interest groups, some conventional alfalfa growers, some organic alfalfa growers, and some members of the public requested the following information or assessments regarding trade impacts of GT alfalfa included in the EIS:

- What will the effects of widespread contamination with unwanted GT alfalfa be on exports to Europe of organically certified dairy products and meat in situations where the importing country or group of countries does not permit feeding of GT alfalfa for these products
- What are the effects of other products of the widespread use of GT alfalfa
- One commenter stated that in 2007 FGI bought a seed production facility in Alberta, Canada to produce GE free alfalfa seed for sensitive markets. The commenter wants to know why would the company that is in charge of trait stewardship of GT alfalfa, that knows the GPS coordinates of every seed and hay field, and has placed every GE alfalfa seed production contract feel the need to purchase their first seed production facility in another country in order to produce alfalfa seed for sensitive markets?
- Will GT alfalfa eliminate sales of the beef to foreign countries
- A thorough economic review of the GT alfalfa trade impacts on export markets.
- Will APHIS avoid relying too extensively on economic data provided by Monsanto and FGI due to their vested interests in GT alfalfa

10. Mitigation/Coexistence/Farmer Choice Issues

Coexistence possibilities

Two national grower organizations commented on the issue of coexistence between GT, conventional and organic alfalfa. These organization stated concerns must be addressed in a

sensible, reasonable and practical manner, and detractors of biotechnology overlook the fact that coexistence is not an offshoot of biotech crops. Other comments

- For 10 years, biotech corn and other systems have coexisted with appropriate control measures
- Corn farmers have practiced coexistence for years through the side by side production of commodity corn and specialty corns such as white or food grade, or hybrid seed production
- Each of these non-commodity corns has distinct marketing specifications that require controlling pollen flow
- Although alfalfa has certain unique agronomic characteristics, coexistence is still managing pollen flow. Since the vast majority of alfalfa is harvested before a viable seed is produced, coexistence is not an issue.
- While alfalfa seed production does present some additional challenges, we are confident the seed industry can easily modify production systems to maintain seed purity
- Finally, we emphasize that the National Organic Standards still requires organic producers to demonstrate they are employing buffers or other control measures as part of their process
- Whether it is seed production, feed production or food production, we can and we have all existed together in the safe and continued advancement and expansion of these technologies in other commodities for many years, and we are confident that the alfalfa industry can and will do the same under the same responsible yet practical approaches employed by other commodities or industries utilizing the same technologies.

One commenter is very active in international alfalfa seed markets and believes that traditional markets, such as these, should not be unduly disrupted by the introduction of biotechnology. The commenter believes that over time these sensitivities will decrease, but in the interim the industry wants and needs to provide international customers with the products they call for, which requires developing methods, procedures and enforcement that enable coexistence.

A seed grower comments that he has seen the steps involved in minimizing the potential harm to growers who choose not to grow GT alfalfa. The commenter continues: FGI has been diligent in our Best Management Practices training, and in overseeing our production process, and believes the EIS process will further delineate the steps needed to assure that all concerned parties will be protected. The commenter feels that coexistence strategies should be developed that not only protect those who choose not to grow GT alfalfa, but also to protect my right to access the beneficial GE technologies that have been proven safe and effective in other crops.

A university researcher believes that it is more important to ask: 1) Is the risk of gene flow difference in magnitude or impact than any other common neighbor effects, and 2) Can steps be taken to keep contamination to a low enough level so that it does not impact neighbors' markets. The commenter states that there is a whole series of neighbor effects that could impact neighbors, including pesticide drift, runoff from manures, or other effects from neighbor to neighbor, and organic farmers are not immune either: they might have trouble controlling insects that move into neighbor's fields, causing harm. The commenter feels that coexistence between these two methods are technically feasible and steps have been taken by industry groups to assist in this process. However, for coexistence to work, the commenter believes that there must be a

willingness on the part of the parties to make it work: if parties state that coexistence is impossible, I suspect that indicates a lack of willingness to attempt to make it work.

One commenter believes that those who wish to use this technology should have the option. As a grower of both conventional and GE alfalfa for both hay and seed production, the commenter feels that it is possible for all parties to be able to coexist successfully: if this industry is going to compete in the world market and continue to meet the needs of our consumers then we must learn how to use the technology that is available to us.

One commenter believes that the American farmer is a good steward of the land and will use this technology as a management tool to insure delivery of a quality product to the market. The commenter supports this technology and will defend the right of the American farmer to choose to use this technology. The commenter feels that non users of this technology also have the right not to use this technology: user and non users can coexist providing both sides are good stewards of the inputs they choose or not use.

One commenter states that the economic loss to farmers would be great if GT alfalfa is not made available and it is clear the research and science being conducted by government agencies, private companies and universities show the GT technology as being safe to animals, humans and the environment. As an agronomist, it is the commenter's opinion that the current stewardship practices put in place for GT alfalfa can be effective so that all cropping systems can coexist in harmony .

An alfalfa seed product manager support growers rights to choose the right product to maximize profitability on their own farms, whether that is GT alfalfa, conventional alfalfa or organic alfalfa production. The commenter wants others to remember that the majority of producers who use or want to use biotech products have as much of a right to choose what products and technologies they grow as does the small minority of growers who want to grower organic crops and he believes that this point has been overlooked repeatedly in this whole situation.

A commenter states that the technology fees from GT alfalfa are used to finance research and development of agriculture products and crops that will enable the American farmer to be competitive in the future and that the value of the research reaches globally: all alfalfa growers, organic, conventional, and technology, should be allowed to coexist in American agriculture.

One commenter felt that organic and biotech agriculture can coexist and thrive, as they have already done so for many years with no major incidents.

In addition to the potential risks, one commenter believes that the economic and ecological benefits of GT alfalfa should also be addressed. The commenter asks to please remember that the operations potentially negatively are very, very small in number and acreage and therefore, coexistence strategies should be feasible through management measures. For example, the commenter asks if all the farmers east of the Rocky Mountains will be denied the use of the crop because a few operations west of those mountains may be affected, and believes that farmers should have the choice of growing GT alfalfa or non-transgenic alfalfa.

An alfalfa grower commented that growers in the United States should have the freedom to choose the type of forage production system they use whether it be GT, conventional or organic, each of these production systems can coexist with proper management. The commenter believes that proper management is the key to employing any advanced technology whether the result of crop chemicals, biological agents or genetically modified technologies to be able to use the new technologies sustainably.

One alfalfa grower stated that we definitely need the right to choose and there is definitely room for both those who want to grow crops and livestock as of one hundred years ago, and those who want to grow for the needs of the present and into the future. The commenter asks to please allow us that right to choose and when I say us, I mean me ,my son and my grandson, who farm this operation, along with those who choose the organic way.

One farmer wrote to say that there is certainly room to coexist and that should be the name of the game; the side that wants no new biotechnology is dealing with a perception that organic is the only good food produced and that anything else is bad.

Coexistence implementation

Many GT alfalfa growers, conventional growers, and other farming interest suggested various ways to implement coexistence:

- The Crop Improvement Associations in the states can help control or define the areas that the two crops are being grown
- Seed companies and NAFA can work together with the Crop Improvement Associations to help develop criteria for GT and conventional seed, similar to onion seed and carrot seed production.
- An in-depth industry discussion is needed to plan and provide coexistence. A plan should include best practices education for growers, open communication and cooperation regarding what is planted on alfalfa fields, suggestions from the non-GE industry to develop best practices guidelines for their industry, and respect for opposing viewpoints.
- “Best practices” to keep any contamination to feral alfalfa or a neighbor who may be an organic grower to a tolerable minimum. All farmers learn to tolerate their neighbors farming practices.
- Good stewardship, courtesy and communication, and separation of fields.
- Stewardship practices already exist will ensure GT alfalfa, traditional and organic alfalfas coexist successfully.
- GE-free production areas, independently funded research, industry cooperation and legal enforcement by State Dept of Agriculture or Certifying agencies
- Identify critical steps in the development, production, conditioning, and shipment of alfalfa seed and develop a working plan that specifies, in some level of detail, actions to be taken to ensure our ability to produce, condition, and ship GE-free seed.
- A three to five mile GE-free zone to isolate GT alfalfa and conventional production.
- Adoption of usual and ordinary agronomic practices, particularly with regard to the timing of cuttings of alfalfa in the field, to eliminate or reduce to minimal trace levels the presence of GT alfalfa in the fields of organic growers and, vice-versa, the presence of organic alfalfa in the fields of growers of GT alfalfa.

- Several state agricultural departments and university extension services have developed coexistence programs and guidelines that farmers can adopt to eliminate or reduce the presence of GT alfalfa in organic alfalfa and vice-versa.
- Before planting GT alfalfa, a grower went to the State Department of Agriculture and got a list of all certified organic growers, and informed all neighbors within a three mile radius. The growers stated that he received no complaints from neighbors.
- Common sense approach, practicality, and stewardship
- Good communication with neighbors, good seed, and requires an understanding of gene flow and how to maintain seed and hay purity
- A commenter stated that coexistence strategies for alfalfa production systems have been developed and tested by growers and the seed industry with input from seed and hay exporters, growers, processors, seed companies and public scientists. For example, the science-based information outlined above was published and disseminated at grower (National Alfalfa Seed symposiums) and seed industry (California Seed Association, American Seed trade Association) meetings prior to commercialization of GT alfalfa in 2005. For example, over 3000 publications were disseminated at the meetings over the past 3 years. Specific stakeholder meetings were held and reported on in ID and CA to develop Best Management practices. Recently (October 10th, 2007), a meeting was held by the National Alfalfa and Forage Alliance to specifically address coexistence in alfalfa. At these meetings and currently, best management practices are being refined that will allow farmers to coexist and have a choice in what production system is best for their particular markets.
- Multiple commenters suggested establishing a ‘tolerance’ or a ‘level’ that could be found in non-GT or organic alfalfa.
- Prohibit the production of GT alfalfa seed within 15 miles of conventional seed production and banning the production of GT hay within 10 miles, with the stipulation that any GT hay within 15 miles must be harvested before it is pollinated. Any remaining concerns can be dealt with by localized regulation for specific areas, such regulation should be implemented at the state or local level.
- Work with State Department of Agriculture to formulate a draft rule and establish a control zone for alfalfa production area.
- Coexistence across production systems is process driven as are the NOP and seed certification programs.

Coexistence concerns

One commenter felt that in the absence of both strong collaboration and cooperation between the industry stakeholders or the establishment of mandatory regulations enforceable by a recognized authority, the alfalfa industry will continue to struggle with the coexistence of biotech and conventional alfalfa.

A conventional seed grower recounted the efforts of a group of growers that petitioned a State Department of Agriculture to develop a GE-free production zone under the control of a local growers board, and that the zone was denied due to the fact that GT alfalfa was not considered a “pest” under state statute.

One commenter stated that the organic food industry is a growing sector in the agriculture community and for FGI and Monsanto along with APHIS to be so cavalier in expecting the organic industry to protect themselves from errant gene flow borders on being criminal.

One commenter felt that GT alfalfa would endanger conventional and organic producers by introducing a questionable technology in a crop that is not studied enough to know its impacts.

An academic states that the proposed topics for the EIS includes a number specifically addressing the potential impacts on the organic agricultural sector of the introduction of GT alfalfa and this is primarily directed toward the issue of potential impacts due to low level or adventitious presence of GT alfalfa in organic seeds or hay products. The commenter believes that it must be noted that NOP rules do not establish a threshold for such presence and specifically state that the organic status of such products is not affected by such inadvertent and low-level presence. The commenter states that the inclusion of a ban on use of GE crops in the NOP rules was not mandated by USDA or APHIS, but was rather demanded by the organic community, and therefore this is a self-imposed ban by a subset of agricultural producers with the intent to differentiate products in the marketplace. To the commenter, it seems inappropriate for a study whose mandate is to assess environmental issues to include impacts on voluntary marketing strategies in its scope.

An interest group states that GT alfalfa must not be deregulated absent a convincing demonstration that growers can be assured of their continued option of growing non-GE alfalfa. The group believes that the right to grow non-GE alfalfa is not limited temporally or geographically, and GT alfalfa is not to be deregulated if a reasonably foreseeable impact of the deregulation is the elimination of the option of farmers living in any region of the country to continue growing non-GE alfalfa, in the near or longer term future. The group feels that the right to grow non-GE alfalfa is also not synonymous with the right to grow alfalfa that is contaminated with GE alfalfa at “negligible levels” due to “inadvertent gene flow,” and thus, APHIS should formulate an alternative that analyzes the contamination issue where the standard is zero tolerance for contamination.

Coexistence assessments

Related to coexistence, interest groups, some organic farmers, and some academics requested the following assessment to be included in the EIS:

- What will the effects of widespread contamination of geographical areas with unwanted GT alfalfa be on farmers desiring to transition into certified organic operations that are for the purpose of growing organically certified alfalfa
- What are the environmental effects of making it more difficult for a farmer or rancher to operate as an organically certified produce, that result from widespread GT alfalfa production and contamination
- An academic stated that if, as implied by the court’s ruling and by its inclusion in the NOI, the impact of GT alfalfa on organic producers must be considered in this government action, then one must ask whether the certification of organic farms and farmers should also be subject to the same consideration
- How are the rights of ranchers, farmers and others to use their land affected by the unwanted invasion of the GT alfalfa products to be introduced into the markets

- If it is established as precedent that economic impacts of the introduction of new agricultural products or practices must be considered as environmental impacts, as per the court's ruling in the GT alfalfa case, then it follows that a new organic farmer should be required to assess the potential impact on neighbors of the decision to seek organic certification.
- What are all the environmental effects of driving family farms out of business by making the organic farming alternative more difficult due to permitting use of GT alfalfa, both alone and in the context of extensive use of GT corn, canola and other crops
- Can APHIS define what it means by the term "coexistence" of organic/conventional alfalfa as to whether its a scientific term or an APHIS policy position
- It is incumbent on APHIS to also consider the economic consequences of allowing the self-imposed marketing preferences of one sector of the agricultural landscape to restrict the economic opportunities of other sectors.
- Has APHIS conducted a survey of organic or conventional alfalfa farmers as to their views of the meaning of "coexistence" with GT alfalfa
- What is the difference in the perceptions of "Coexistence" between organic or conventional alfalfa farmers compared to GT alfalfa farmers
- Whether any of the potential negative environmental and economic impacts resulting from the deregulation of GT alfalfa can be mitigated and the likelihood that mitigation measures will be successful – that is, whether "coexistence" is practical or possible.
- If the EIS were to propose specific mitigation procedures that would restrict the opportunities for farmers to grow GT alfalfa due to proximity to organic farms, then the economic impacts of that decision should also be included in the study. Such an analysis might conclude that the NOP should be required to conduct an EIS before certifying additional organic farms if their presence would economically injure nearby conventional farms due to restrictions imposed on their crop choices.

11. Effects of GT Alfalfa on Animal Production Systems

A GT alfalfa farmer growing GT alfalfa for dairy cow production stated that GT alfalfa is free from weeds which defrayed the costs of production due to not having to purchase additional hay for their animals or add protein to supplement their feed as is needed in lower quality hay.

Some commenters felt that GT alfalfa brings improved RFV's, more milk to dairies, higher quality beef, and numerous other benefits. One grower attached a recent study that shows that GT alfalfa has no effect on feed intake, milk composition or milk production in dairy cattle.

GT alfalfa growers commented on the ability of GT alfalfa to keep out noxious weed that injure, maim or kill cows and cattle, including cheat grass and nightshade.

One commenter states that he would rather be eating meat from cattle that is eating alfalfa that has been sprayed with glyphosate than all of the other labeled chemicals, is in favor of the labeling of GT alfalfa because we will have a lot better quality feed for the meat that we eat.

Some animal producers feel that animals will refuse to eat GT alfalfa.

Interest groups, some organic and conventional farmers, and some members of the public requested the following information or assessments regarding animal production systems and GT alfalfa included in the EIS:

- What percentage of the pesticide formulation ingredients used on the alfalfa crop show up in the milk of dairy cattle fed this material
- Does the presence of this pesticide alter gene expression in livestock consuming GT alfalfa with the highest application levels of this herbicide and the adjuvants of the formulation
- If there is alteration in gene expression in livestock, can it be transmitted from one generation to the next
- Can the presence of glyphosate in the alfalfa crop alter the numbers of primary follicles in heifers, which would alter their reproductive output
- Should organic livestock agriculture gain the public perception, both domestically and internationally, that it has been contaminated by GE organisms, the public appetite for organic food may be substantially harmed and farmers economically injured
- To what extent will the level of production of organically certified livestock be affected by the use of GT alfalfa and what will the environmental effects of such changes in volume of production be
- An animal feeding trial for multi-generation should be conducted involving both male and female of the species. This should be done outside the influence of Monsanto or FGI.
- What are the effects upon producers and the public of making overall grazing and other use of lands by organically certified farmers and ranchers in circumstances where volunteer and stray GT alfalfa appear in fields which cause additional work or even cause disqualification of a field for organic production
- How will feeding GT alfalfa to beef affect the rating of the beef? Can it be sold as natural?

12. Effects on Food & Feed

Commenters representing organic farming interests, members of the public, and interest groups questioned the safety of GT alfalfa as food or feed. Issues raised and assessment requested for the EIS included:

- Feeding alfalfa to animals treated with glyphosate because glyphosate residues that may be harmful to them
- Use of alfalfa sprouts for human consumption and the use of the CaMV promoter
- What are the effects on children's and others' health nationwide from consumption of meat and, separately, milk where the livestock in question have consumed GT alfalfa including the effects of increased anxiety not knowing what the effects of GT alfalfa are
- What is the period of years likely to be needed for the scientific community to detect higher rates of allergies, cancer and other maladies that result from animal consumption of GT alfalfa and human exposure to GT alfalfa
- What are the effects on children's and others' health nationwide from driving organically certified ranchers and farmers out of business by making it more difficult to produce alfalfa that can be organically certified

- Some commenters were concerned about the effects of GT alfalfa, the nutritional quality of GT alfalfa, or the effects of GE foods in general, on livestock and human health, or were concerned that the effects were not well studied
- Genetic engineering corrupts organisms, and thus results in poisoned food
- GE alfalfa seed must not be sold to be used for alfalfa sprouts
- What is the impact of non-GT alfalfa mixed hay cut at bloom for balanced nutrition-beef cattle, horses, sheep, etc.
- One commenter felt that we need to stop genetically modifying products that go into our food chain because we are what we eat
- What is the effect of feeding GT alfalfa to the mother and calf, hogs, and poultry, and should include alfalfa in its most common forms
- Impact of the glyphosate-resistant gene in alfalfa, by direct comparison with isogenic non-glyphosate resistant lines, grown in various soil types on:
 - Nutrient uptake efficiency (N, P, K, Ca, B, Cu, Fe, Mg, Mn, Mo, Zn)
 - Root exudates impact on the rhizosphere micro flora
 - Nitrogen-fixing Mycorrhizae, pathogens, synergists
 - Nutrient cycling organisms for: Fe, K, Mn, S, etc.
- Impact of glyphosate applied to GT alfalfa compared with non-GT alfalfa on:
 - Yield, nutrient quality, mineral content
 - Rhizosphere organisms: nodulation, nutrient availability
 - Diseases - pathogens, biological control organisms
 - Sustainable production - soil fertility, drought stress, maturity, over-all cost differential with anticipated micronutrient and biological amendments, resistant weed control, etc.
- Impact on subsequent crops in the rotation:
 - Establishment, nutrition
 - Growth and productivity
 - Degradation and persistence of glyphosate and its metabolites from root exudates at root depths of alfalfa
- What are the negative impacts on food or feed value or quality from the use of glyphosate containing organic chemical impurities detectable in batch quantities of herbicide produced such as formaldehyde, N-Nitrosoglyphosate, and insolubles?
- Does the presence of detectable or undetectable glyphosate residues effect the taste of alfalfa when it is processed into food products?
- Does the presence of detectable or undetectable glyphosate residues effect the nutritional quality of alfalfa when it is processed into food products?
- An interest group states that a person has to be ignorant to believe that a smorgasbord of toxic agricultural chemicals in the foods is safe to consume.
- Compositional assessments submitted to USDA and FDA by Monsanto are not adequate
- Determine the current impact of weeds on animal production and animal health, and if this new technology decrease animal performance or welfare, or improve it
- One group wants carefully controlled, long-term animal feeding studies, with toxicological endpoints, to assess GT alfalfa for potential adverse effects on animal health

Alfalfa farmers growing GT alfalfa, members of the public, and farming interests commented on the benefits and safety of GT alfalfa. Issues include:

- GT alfalfa produces higher quality alfalfa with greater yields and improved quality that could be marketed to dairy farms for feed
- Glyphosate will kill certain weeds that are harmful if consumed by ruminants, thus increasing the safety of the feed
- GT alfalfa is safer to produce our meat or milk because of the proven safety and effectiveness with years of use of glyphosate in other crops
- Research indicates that GT alfalfa should be safe to use in the United States, and should be registered for use
- No peer reviewed scientific studies have presented any data suggesting or proving any health or safety risks in the use of (feeding) GT alfalfa
- Farmers goals are to improve the environment and feed for the animals they raise as far as that goes the people they feed as well. GT alfalfa is providing that tool for these producers to so that.
- The GT gene has been in our food chain since the release of GT soybeans. It is very likely that if you eat meat, drink milk, or eat eggs, those animals have been raised with protein sources derived from GT crops. It is a sound, proven technology that should be utilized in alfalfa.

13. Worker Safety

Many GT alfalfa farmers, public agencies, and members of the public believe that One chemical exposure to the application personnel and the growers is greatly reduced by being able to use the safe and reliable chemistry of glyphosate.

One farmer stated that using glyphosate not only minimizes the health risks to our employees, but it also reduces the amount of stronger chemicals that our operation uses. The reduction of chemicals and the types of those chemicals reduces environmental exposure and our costs of production.

An organic association believes it is important that the EIS study the potential health impacts of glyphosate exposure on the users of the chemical, which may include farmers, farm laborers, and the children of the applicators.

14. Alfalfa Agronomic (Farming) Practices

An academic states that alfalfa is grown in almost every state, and is a strategic crop for the United States not only because of its direct commercial value, but also because of its environmental-biological impact in developing soil fertility and structure through its deep tap-root growth habit, fixation of atmospheric nitrogen, and perennial leguminous nature for erosion control. The commenter believes that the value of these environmental functions in crop rotations and sequences may far exceed its commercial value for hay, and Any loss of alfalfa production efficiency or quality can have serious consequences for sustainable crop and animal production, with subsequent deleterious impacts on human nutrition, health, and well-being.

One commenter representing academia and another comment from a GT alfalfa farmer stated that GT alfalfa performed similarly to conventional alfalfa, could be managed similarly to conventional alfalfa, and could be controlled similarly to conventional alfalfa.

GT alfalfa farmers described how they use GT alfalfa and glyphosate on their farms:

- We must constantly monitor for noxious weeds. The highway department sprays a couple of times during the summer, may not spray before weeds go to seed. I can spray along the roadway and up to the edges of the alfalfa fields without worrying about the glyphosate killing the edge of the GT alfalfa fields.
- If thistles come up in GT alfalfa, we can take a hand sprayer and hit the thistles, and not kill the alfalfa. That sure beats taking a scythe and cutting that area by hand before the thistles bloom!
- I can grow higher quality hay with very few weeds in it. When the alfalfa does not have competition, it does not thin out as fast. So, I do not have to rotate crops as often. Hay is my main crop, so rotating crops is a detriment and is expensive.
- We can spray the field with glyphosate to kill all the kochia, pigweed, morning glory, thistles, quack grass, and other problem weeds while the alfalfa is small, so that we can get a good, thick stand of alfalfa that will not allow other weeds to compete with it. Then, the alfalfa controls the weeds so we do not have to spray again. Spraying all weeds cannot be done in a conventional field of alfalfa, so the small alfalfa plants must compete with all of the weeds to become established.
- The weed control provided by the applications of other herbicides besides glyphosate is very good for the spectrum of weeds in our area. The main problem we have seen is that the application of these herbicides is very hard on the young conventional alfalfa and it takes over a week for it to recover from the effects of these herbicides. Growth is minimal in the conventional fields during the recovery process and the GT alfalfa does not experience this, since the application of glyphosate does not affect the alfalfa.
- One of the largest problems we have in our alfalfa stands are grasses. Usually by the second or third year, all our fields have some level of grass present along the drain end of the field or in the higher traffic areas. Glyphosate is an excellent grass herbicide and we followed our establishment spray in the tolerant fields with a summer application to control any additional weeds.
- We often see water grass and nuts edge in isolated parts of a field and with the GT alfalfa, we can spot spray these areas very effectively.
- Winter weed control is very important for the longevity of our alfalfa stands, and we are always concerned when applying restricted use chemicals. We have a closed mixing system and other safety measures in place, but not using dangerous chemicals at all is by far the safest practice. We would also like to reduce our use of some other herbicides because of its potential to leach into the groundwater and move in field runoff. The GT varieties allow us to use only glyphosate to control weeds and its chemistry is much safer than that of some of the herbicides we use in our conventional fields.
- We remove our stands by mechanical means (a heavy stubble disc), so we are not concerned about not using glyphosate for stand removal.
- Alfalfa growers try and harvest their crop in the bud stage but due to weather conditions may have to delay harvest until the bloom stage. Even with late harvest the vast

majority of the alfalfa grown in Nebraska never goes to seed which dramatically reduces any chances of pollen flow.

- One commenter was concerned about whether weather plays a role in gene flow because he states that it takes at the very minimum, another thirty days of the most beneficial weather to make viable seed, in our area its closer to forty-five days. If the weather stays inclement, it will never make seed.
- One grower stated that glyphosate was an unreliable tool for alfalfa stand take-out
- A GT seed farmer practices strict sanitation practices in harvesting and handling seed with extensive cleaning of equipment and separation of seed lots between GT alfalfa and conventional. Seed is put in specially marked bins and separately stored, have three combines, and one is used only for GT alfalfa. Feral alfalfa on ditch banks, road sides and adjacent areas, is sprayed out with a non-glyphosate herbicide. We are very aware of our neighbors conventional both hay and seed fields and adhere to isolation distances that are in excess to what is acceptable, and they are monitored by seed certification officials and others.

GT alfalfa growers, researchers, scientists, and farming interests spoke to the benefits of using GT alfalfa in alfalfa agriculture:

- Significantly more hay in the seeding year when direct seeding
- Extra yield of high quality alfalfa in the seeding year alone pays for the cost of the technology and seed
- An alfalfa product manager of a seed company encouraged growers to plant GT alfalfa on their fields with the most severe weed problems to put it to the maximum test possible. He did not find any grower who was disappointed with their weed control using the technology in these situation.
- Primary benefits of GT alfalfa were considered to be higher tonnage, better weed control and better quality resulting in higher profitability for the grower. GT alfalfa is beneficial because it can increase the longevity of the alfalfa stand.
- A researcher discovered that weeds were more competitive and reduced stand and yield compared to GT technology, and there is more yield reduction to alfalfa from the commonly used herbicides than we had previously known, because now there is an additional control better than an untreated check.
- One alfalfa grower felt that because many alfalfa fields in southern Minnesota are right next to GT soybean and corn fields, farmers could spray glyphosate right next to the alfalfa field without injuring either crop and control the weeds.
- One alfalfa grower felt that GT alfalfa would reduce soil and water erosion, and the benefit to the environment will be greater than the weed control benefit in alfalfa.
- Some growers feel that GT alfalfa seed is just one example of raising more and better food per acre
- One commenter felt that the technology will keep growers in the East growing Alfalfa vs. trucking in alfalfa grown in the West, and GT alfalfa will save our entire system time, fuel and effort

A nationwide trade association representing alfalfa and forage producers in 23 states submitted the Best Practices for growing GT alfalfa.

An alfalfa grower states that with all of the alfalfa plants that are growing wild and plants that are not being harvested in a timely manner are really causing a problem, but only in GT alfalfa seed production. My question is why have all these issues not been brought up before? Growers have always paid a premium for pure seed or a certain variety. Why have we not had any issues in the past with alfalfa plant escapees or one variety of alfalfa getting crossed with another? The seed industry is very careful to isolate and control the potential of cross contamination with various guidelines and certain protocols. The seed industries standards are already tough regarding seed production and the rules that are applied to GT alfalfa are 90 times as tough.

A seed grower stated that his production contract states: "The Company" recognizes that circumstances outside the grower's control may lead to an adventitious presence from an unknown origin within the seed of a genetically modified organism ("GMO") or other. "The Company" considers any such presence up to 1 % to be adventitious. If an adventitious presence exceeds 1%, "The Company" will take possession of the seed and shall pay the grower a price to be negotiated.

One commenter states that the most important factor for hay growers to maintain purity is to begin with certified seed for planting.

One commenter felt that the de-regulation of GT alfalfa will have very little effect on the production of other crops because the primary factor in alfalfa acres is the demand for hay. The commenter believes that the need to feed dairy and beef cattle or an ever growing recreational horse market will determine alfalfa acres, not whether GT alfalfa is de-regulated or not, and that these are the same market influences that have driven corn acres: demand for ethanol, high fructose corn syrup, and animal feed have pushed the increase in corn, not the acceptance of the GT trait.

A cotton association wrote in to discuss the potential similarities between GT alfalfa and GT cotton. They felt that a decrease in herbicide use is found in GT cotton and expects the same for GT alfalfa.

Some conventional and organic alfalfa growers, members of the public, and interest groups commented on concerns or problems with the farming of GT alfalfa:

- Other herbicides besides glyphosate would be used to take out GT alfalfa, some conventional alfalfa growers do not want to lose glyphosate as a tool for stand take-out, and there would be damage caused by drift of these other non-glyphosate herbicides
- If the neighbor sprays glyphosate on his GT alfalfa, and the spray drifts, it will kill my alfalfa
- One group wanted company personnel on hand to assure minimum seed mixtures and felt that seed transported off farm should be tarped to avoid roadside propagation of feral plants
- One group wanted reporting of GT alfalfa plantings to local crop improvement no later than 7 days from date of delivery of parent seed to producer
- For a non-GT alfalfa grower, GT alfalfa is a weed just as damaging as morning glory, Canadian thistle, etc, depending on the buyers demand or seed contract stipulations

Related to agronomic practices in alfalfa farming, interest groups and members of the public requested the following assessments be conducted or information stated in the EIS:

- Volunteer alfalfa in seed production has not been addressed
- What plant back restrictions should be used for GT to conventional alfalfa seed rotations
- Is it possible to plant conventional alfalfa after a GT seed production
- Independent study is required to confirm that isolation distances are adequate
- Potential map of organic alfalfa usage extends across much of the United States and must be considered as an aspect of the EIS
- What about the hay grower or seed grower that has GT alfalfa contamination in his field. How can they eliminate the contamination in his crop?
- What are the environmental effects of prolonging alfalfa fields
- An interest group wants to know the role APHIS will play in surveying organic and conventional farmers on their preferences in regard to farming practices, impacts of GT alfalfa on their farming practices, their current, future, and past farming practices

15. Regional Production Differences

Some conventional alfalfa farmers were concerned because common production practices in South Dakota are to maximize the size of our first and sometimes only cutting of alfalfa; thus alfalfa is midbloom or sometimes full bloom before cutting. For them, the second cutting alfalfa is mostly nonexistent if rainfall is limited, and alfalfa is too short to cut but often blooms for several months then produces seed. Thus, for these commenters, seed crops of common alfalfa is a very good cash crop, often worth more than the hay crop.

One commenter was concerned about the bee restrictions for growing GT alfalfa. He felt that bee production in the northern United States is very dependent on alfalfa for honey production because sites of hives are positioned close to alfalfa fields. I believe GT alfalfa will wipe out the conventional common seed producers.

One beekeeper was concerned because in the Midwest, alfalfa is our major source of honey. When it is too dry in the Midwest to make hay, the commenter believes that farmers still have the option to go for a seed crop, and this has been a great source of additional revenue in an already dry year: we make honey off the blooming alfalfa and they get a seed crop.

One commenter from the Midwest stated that alfalfa grown in this area is grown for feed, and the highest feed value from alfalfa hay is when it is cut in the pre-bud or bud stage. The commenter believes that with this strategy, no viable seed can be produced nor is any pollen available for bees to carry to non-glyphosate fields. His comment continues: if harvest is delayed and the alfalfa blooms, viable seed is still not produced because harvest and drying of the hay prevent development of viable seed. If the weather is so bad that harvest cannot take place, the commenter feels that the conditions also limit the ability of bees to forage.

One commenter felt that GT alfalfa would be a good choice for Tennessee and mid-South alfalfa growers without impacting their neighbors. Most of our alfalfa growers are dairy farmers and use the hay on farm, or sell to their neighbors.

A conventional alfalfa farmer write that although the argument has been made that a "barrier" could be created, this would be impossible with alfalfa in the Imperial Valley because of pollen flow and alfalfa is planted in a patch-work manner where someone could rotate a crop out in a surrounding field and plant GT alfalfa and contaminate a conventional alfalfa field. The commenter believes that if GT alfalfa was to be planted in the Imperial Valley, due to cross-pollination, we would automatically lose 85% of our market because we sell to GE-sensitive markets and this would effective destroy our market for our conventional alfalfa seed.

16. Agri-business Concerns

Some commenters question the long term security of the nation's food supply in light of Monsanto's quest for monopolizing control of seed through the patents of hybrid, genetically engineered & pesticide dependent products and the purchase of existing vegetable seed company's nation wide. Some commenters were also concerned that alfalfa seed was only held by FGI and/or Monsanto.

Some commenters were concerned that USDA is only deregulating GT alfalfa because it is a product of big agribusiness, specifically Monsanto.

One commenter was concerned about the legal system of patents on artificially manipulated plant genetics that allows holders of such patents to seek damages against farmers who harvest seed that may have been contaminated by plants on which there is a patent. Further, the commenter believes that actions have been taken by holders of such patents and farmers have been significantly damaged economically.

One commenter believes Monsanto has been issued many fines for the work they do and so in my opinion it is risky to allow this profiteer to let this product be used in a wide area so quickly.

One commenter is concerned that the governments of world are shoving genetically engineered food down our throats with no labeling or vote on that we even wish to be eating, and that the government has helped Monsanto by letting them get away with false tests that where done by Monsanto own employees.

One commenter's concern is that if we continue to regulate and over regulate everything, it will not be long and American agriculture will be done with; the fact of the matter is that without progression (GE crops, better chemicals, and the best technology available), it will not be long and we will not be able to compete on the world market far less be a leader.

An interest group was concerned about the value of studies provided by Monsanto and wanted to know the funding source of all authors on publications and felt that the public would be better served with this information. One commenter believes that Monsanto can hire an army of people to manufacture crop safety data, as well as post comments.

An interest group felt that APHIS possesses a governmental zeal trumping science and consumer interests in supporting GE crops such as GT alfalfa despite serious questions about Monsanto's own glyphosate studies and whether GT alfalfa is needed at all. The commenter believes that

there is the inherent bias in Monsanto's research studies, that they are flawed by design, and flawed by analysis, therefore, questions arise over how much of Monsanto's glyphosate research has actually been subjected to external peer-review and published in journals.

One comment wanted the EIS to show the economic impact on seed and feed costs if all alfalfa were controlled by GE seed monopoly, and this commenter also felt that property rights are impacts on growers of non-GT alfalfa.

One commenter feels that it is unreasonable that the government would allow introduction of a situation that puts significant power in the hands of a large corporation to materially harm large numbers of small businessmen (farmers) in situation where these small businessmen have no malicious intent.

17. Continuing the Use of Biotechnology

Some commenters felt that as world demand for food increases and available land and resources decrease, higher yields per acre must account for this deficit. Advances in technology, such as GT alfalfa, must be integrated into agriculture in order to move towards sustainability. The commenters feel that the bottom line is that this technology is safer for the environment, the grower, and the consumer, and it is also can help increase production on the current acres farmed. One commenter even felt that the American farmer wants the ability to use this great technology in their quest to continue to grow high quality alfalfa to feed their herds and feed the world.

Some growers are concerned that the removal of GE crops would not allow the country to feed itself and cut down the use of foreign oil.

One commenter only wanted genetic-engineering to be used for disease resistance and flavor enhancement.

One commenter felt that the whole situation with GT alfalfa is similar to BST; we have a safe technology and a few pin heads screw up the whole works. The commenter feels that if GT alfalfa is not approved for use, we can blame of our government for failing to use common sense.

A academic stated that herbicide-tolerant crops produced by other methods (e.g., mutation) did not require an EIS prior to commercialization, yet the potential for development of weeds resistant to those herbicides is greater than that for glyphosate. The commenter asks why should those questions be included in an EIS only required of crops developed using recombinant DNA methods, while the same environmental issues arise with crops having similar traits developed by other methods? The commenter stated that the underlying principle of the GE regulation in the United States is claimed to be based on the product, not on the process, and by including these questions about development of herbicide-resistant weeds only for GE crops and not for those developed by other means, APHIS is not being guided by its stated principles.

A seed grower stated that throughout the history of modern agriculture there has been resistance to transformative technologies, such as steel plows, sprinkler irrigation, commercial fertilizer,

tractors, and reduced tillage practices, and asks how could we feed the world if new technology was not available to expand productivity.

An alfalfa grower believes that the American consumer wants quality food that is affordable and safe, and the American agricultural producer wants to supply the food to meet these criteria and needs to make a profit. To meet the increasing demand for food and fiber in the United States and abroad, the commenter believes that the American producer needs all of the tools available to produce an economical, safe, quality product at a reasonable profit and GT alfalfa is one of these tools. Further, the commenter believes that if all American producers were to switch to “organic” farming methods and abandon the new technology that has been made available this past 100 years we could not even feed the United States, let alone the rest of the world.

One commenter stated their contention that growers in the United States should have the ability to choose GT alfalfa varieties if they are to remain competitive in the world today and still be able to efficiently meet the demands for quality hay products.

Many farmers commented that if the soybean and corn plants can be modified with no problems feeding it to animals, why not alfalfa.

Some commenter felt strongly that farmers are held captive a minority (“environmentalists” and “so-called do-gooders”) that tell the farming community what to raise. These commenters felt that the regulations and court orders make it harder to make a living.

An alfalfa producer believes that we need GT alfalfa as one of the tools to help supply high quality forages to an ever increasing market, there is a shortage of quality alfalfa hay, and GT alfalfa will enable us to get maximum production the seeding year and encourage producers to keep alfalfa as part of a diversified crop production system.

One commenter believes that there is lots of room in this world if we just learn to be tolerant and accept new ideas.

18. Comments on the EIS Process

APHIS received requests for extension to the Notice of Intent public comment period, and numerous scientific publications demonstrating the potential for gene flow between alfalfa fields, pollinator behavior, food and feed issues related to GT alfalfa, weed management issues in GT alfalfa, glyphosate safety studies, and studies related to various environmental impacts.

Some commenters stated that the questions posed in the NOI were adequately developed by APHIS.

One commenter felt that the EIS should address a fuller range of topics than is required in the court order, and discussion should be open to findings and reports completed after the EA was completed in 2004. One aspect requiring fuller comment, according to the commenter, is an apparent bias toward unsupported opinions rather than references to relevant empirical studies, therefore, is imperative that the new EIS should be produced by a fresh group of APHIS staff

members who had not been involved in the original EA, those new members should be committed towards full and unbiased reporting based on empirical evidence.

A farmer using organic methods to grow alfalfa felt that the proposed scope of Environmental Impact Statement was excessively narrow.

A farmer using organic methods to grow alfalfa asked what alternatives for regulation exist other than those set forth in the Notice (whether or not such alternatives require legislation or revised regulations of the USDA)? What is the balance of pros and cons of the USDA authorizing the use of the GE products in question.

One commenter wondered why the comment site did not show some of the comments and regulations website seems inadequate and negligent.

One commenter wanted better public announcement of dockets open for public comment.

One commenter wants to know that a comment comes from the heart and from a protective instinct for American citizens, and not from money and greed desire, thus the commenter asks that APHIS require that a commenter identify whether he has any financial interest in what he is commenting on.

One commenter feels that considerations should be trait-based rather than process-based and that the EIS should address scientifically valid risks, not perceived or precautionary risks.

A farmer growing organic alfalfa asked what role should scientific uncertainty and numerous issues dealing with genetic modification (health issues, production issues, marketing issues, pest and weed issues, and others) have upon assessing environmental impact of the decisions in question that are the subject of the EIS.

An interest group stated that APHIS needs to ensure that legitimate external peer-review is conducted of the scoping process so the EIS is good science and not as inadequate as the Environmental Assessment was on GT Alfalfa.

A law professor stated that NEPA, and EISs under NEPA, are not meant to provide an analysis of creating a protected or protectionist market for any economic group, including for organic farmers, and NEPA does not and should not guarantee that organic farmers can satisfy any particular market demand. The commenter feels that if there is a market demand for 100 percent free organic alfalfa or alfalfa seeds, it is the responsibility of organic growers and their marketing agents to bear the costs and the burdens of meeting that market demand.

A farm bureau stated that while marketing and export concerns are extremely important, and NEPA requirements must be met, it is our view that these issues are best addressed primarily by the market place.

A commenter believes that GT alfalfa may have the potential to increase the acreage of alfalfa grown in the United States, and therefore, the possible benefits of expanded alfalfa acreage due to GT alfalfa should be assessed.

19. General Concerns or Other Potential Impacts Not Mentioned

A beekeeping group urge not only that genetically engineered (GE) Roundup Ready alfalfa not be deregulated, but also that existing plantings of GE alfalfa be destroyed.

The president of a seed grower association states that he had the opportunity to raise organic alfalfa for seed, but has declined because the negative weed and insect impacts that would have occurred without the use of herbicides and pesticides, and only being able to raise just a few acres because of the hand labor required. The commenter believes that this is not something a real farmer can afford to do.

One commenter felt that GT alfalfa would endanger conventional and organic producers by introducing a very questionable technology in a crop that is surely not studied well enough to determine its impacts. Other commenters were concerned about diminished biodiversity.

A GT alfalfa grower stated that currently all of my alfalfa seed production is GT and he follows all of the “best practices” guidelines set forth by the USDA and FGI. The commenter also stated that in the past 3 years of dealing with this GT crop I have not had one complaint from any neighbor, farmer, rancher, or consumer in my area.

An organic alfalfa grower asked if GT alfalfa is a product for which there is no legitimate use.

A grower believes that most environmental concerns about GT alfalfa are without adequate merit, there are many millions of acres of GT corn and soybeans grown in America every year, and this has not lead to any environmental catastrophe, although that was predicted by many of the same groups who oppose GT alfalfa. The commenter believes that, GT crops have become an integral part of farming practices that reduce the tillage and environmentally harsh and persistent herbicides, and GT alfalfa will be no different.

One commenter felt that a key aspect of the deregulation decision is to compare current practices (organic, conventional), with practices which are enabled by this technology (GT), and to understand the relative advantages and disadvantages of current conventional methods with the GT approach in terms of environmental and market impacts. The commenter feels that the risk is not only from the new technology, (which are in some cases unknown or speculative), but the risks of current (chemical and non-chemical) weed control methodology must be taken into account, as well as the (not unsubstantial) risks of failing to control weeds by any method.

One commenter was concerned that a genetically modified crop seed be eaten by a bird; if that bird got ill, and subsequently infected poultry, and then spread to humans, if that is what caused avian influenza.

One commenter stated that growers of GT alfalfa found no negative impacts to surrounding fields or animals for growing and feeding GT alfalfa.

A university scientist submitted his testimony given during the court case that ultimately ended with the decision to complete this EIS. His testimony covered gene flow, stewardship, and coexistence strategies.

An organic farmer wants to know:

- What are the environmental effects of introducing into the general environment GT alfalfa which, once introduced, will never be eliminated from the environment.
- What are the environmental effects of damage to the public perception of organically certified products where testing is perceived to be inadequate to detect GT alfalfa as to many products.
- How are all environmental impacts of the various possible decisions affected by the impacts upon production of organically available grain and other production (other than alfalfa) due to past approvals by the government to use GE products with consequent effect on the production of those crops organically.
- What will be the effects on the ability of people of limited means, as well as the public in general, to purchase organically certified products after production of organically certified alfalfa is made more difficult (and expensive) by invasion of unwanted GT alfalfa.

A public interest group requested the following assessments be included in the EIS:

- What is the negative impact to consumers whose preference is to purchase organic alfalfa sprouts and organic alfalfa food products because they seek more certified organic nutritional foods in their diet and seek to avoid eating genetically engineered alfalfa products and will have to avoid all alfalfa products in the future if they become contaminated with GT alfalfa ingredients and no organic alfalfa is available.
- If certified organic alfalfa nutritional food items are contaminated, what will be the economic impacts to the organic food sector and to consumers who want the certified organic alfalfa nutritional food items.

One non-GT alfalfa grower wanted the EIS to consider these environmental impacts (from 0% contamination to 1 % contamination):

- Will this percent be okay to be marketed if between 0 and 1%?
- Due to no fault of my own, if this adventitious presence goes to 10%, is this the point at which FGI sues me for patent infringement, even if they are at fault for the contamination?
- Who pays the tech fee on this? Will I have to pay the full 10% of the tech fee or will FGI pay at the rate at which I pay for the original testing?
- Will these questions have different answers if the percentage grows to 20%?

A conventional seed farmer believes that our government has an obligation to preserve the small niche markets that we have been encouraged to develop over the 27 years that I have been involved in the alfalfa seed business, and we need to respect and preserve the market that the "organic" folks have also worked hard to develop.

An exporter stated that Monsanto has yet to join with the Washington State hay exporters in an educational effort in Japan, to help develop Japanese-language media materials for distribution to Japan's forage industry, and to accompany us to Japan to make face-to-face presentations, answer questions in detail and generally allay the fears and concerns the Japanese forage industry has. The commenter feels that Monsanto is ignoring the concerns of the Washington State hay industry and intends to proceed with their sales plan, whereas we believe Japan's reaction to Monsanto's sale of GT alfalfa seed in Washington State could be extreme, including chances of a boycott or other negative reaction. The commenter feels that the consequences of such a reaction will fall primarily on the shoulders of the Washington State hay industry and on the state's economy, not Monsanto, and Monsanto either does not appreciate, or is not concerned about, the heightened level of Japanese consumer awareness of, and phobia for, GT products, particularly with regard to milk and dairy products and the perceived danger to their children's diets.

One grower considered surface and ground water pollution, potential worker safety issues, and that alfalfa field is in the riparian zone of a river when selecting alfalfa seed. The commenter stated that he is practicing sustainable agriculture, and the use GT technology fit well to my soft/integrated pest management program.

An interest group wants APHIS to conduct a comprehensive study of the extent genetically GE alfalfa has already contaminated organic and conventional alfalfa seed, because such testing would allow the alfalfa seed and forage industries to identify contamination, understand the scope of segregation problems, and educate their customers accordingly.

On commenter asked if there is no evidence of harm after all these years of use how can the USDA possibly recognize something that does not exist.

Appendix E. Acronyms and Glossary

Acronyms and Glossary

A

Abiotic	Non-living, environmental factors such as cold, heat, drought, flooding, salinity, toxic substances, and ultraviolet light.
Acute exposure	Single or short-term exposure to a substance.
Acute toxicity studies	Acute toxicity studies are those that study the effects of a single or short-term exposure to a substance.
a.e.	Acid equivalent; refers to the weight of an herbicidally-active acid.
a.i.	Active ingredient; refers to the weight of an herbicidally-active acid plus its salt.
<i>Agrobacterium tumefaciens</i>	A bacterium that causes crown gall disease in some plants. The bacterium characteristically infects a wound and incorporates a piece of its own DNA into the host plant genome, causing the host cell to grow into a tumor-like structure. This DNA-transfer mechanism is commonly exploited in the genetic engineering of plants.
<i>Agrobacterium</i>-mediated transformation	The process of DNA transfer from <i>Agrobacterium tumefaciens</i> to plants, which occurs naturally during crown gall disease and can be used as a method of transformation.
Allelopathic	Effects to reduce the growth of one plant due to chemicals released by another.
Allelochemical	A chemical produced by a plant of one species that has a detrimental effect on plants of other species.
AMPA	Aminomethyl phosphonic acid; byproduct of the degradation of glyphosate.
AMS	Agricultural Marketing Service.
AOSCA	American Organization of Seed Certifying Agencies.

Allergen	Any substance that causes an allergic reaction.
Autotoxicity	Self-destruction of a species through the production of chemicals that escape into the environment and directly inhibit the growth of that species.
APHIS	Animal and Plant Health Inspection Service.
B	
Bioaccumulate	To increase in the concentration of a chemical in biological systems over time as compared to the chemical's concentration in the environment.
Biotechnology	Making specific modifications to the genome of an organism using techniques based on molecular biology, such as genetic engineering, gene transfer, DNA typing, and cloning of plants and animals.
BNF	Biotechnology Notification File.
Breeding	The process of sexual reproduction and production of offspring. Plant breeding is an applied science for the development of plants suited for the use of humans, rather than their ability to survive in the wild.
BRS	Biotechnology Regulatory Services (USDA–APHIS).
Burndown	Application of herbicide to kill weeds and prepare field for seeding.
C	
CAS	Chemical Abstracts Service. CAS numbers are unique numerical identifiers for chemical elements, compounds, polymers, biological sequences, mixtures and alloys.
CCD	See Colony Collapse Disorder.
CDMS	Crop Data Management System.

CEQ	Council on Environmental Quality.
Certified seed	Seed produced to specific standards to assure purity and freedom from weed seeds and seedborne pathogens, which is used for commercial production of the crop.
CFR	Code of Federal Regulations (U.S.).
Chlorination	A water purification and disinfection process.
Chronic exposure	Exposure to a substance over a large percentage of the subject's life span.
Chronic toxicity studies	Chronic studies are those that study the effects of exposure on a large percentage of a subject's life span, such as daily exposure received by workers.
Colony Collapse Disorder (CCD)	Phenomenon in which worker bees from a beehive or European honey bee colony abruptly disappear.
Companion crop	A crop different than the primary crop for harvest grown in close physical proximity to the primary crop, on the theory that they assist each other in nutrient uptake, pest control, pollination, and other factors necessary to increasing crop productivity.
Conspecific	Belonging to the same species.
Conservation tillage	A broad range of soil tillage systems that leave crop residue on the soil surface, substantially reducing the effects of soil erosion from wind and water.
CP4	Strain of <i>Agrobacterium</i> .
CP4-EPSPS	Bacterial gene (from <i>Agrobacterium</i> sp. strain CP4), responsible for the production of 5-enolpyruvylshikimate-3-phosphate synthase (CP4-EPSPS) that has been inserted into the alfalfa genome to create GT alfalfa.
Cross-pollination	Occurs when pollen is delivered to a flower from a different plant.
D	
DEIS	Draft Environmental Impact Statement.

Deoxyribonucleic acid (DNA)	A nucleic acid that carries the genetic information of a cell. The structure of DNA is two long chains, consisting of chemical building blocks called ‘nucleotides,’ twisted into a double helix. The order of nucleotides determines hereditary characteristics.
DNA	See Deoxyribonucleic Acid.
Donor	An organism that provides a gene or gene fragment used in the genetic transformation of another organism, called the “recipient.”
Dormant variety	Varieties of alfalfa that go dormant in the fall, with reduced growth in response to low temperatures and shorter days.
Dryland seed	Alfalfa seed produced in areas that receive little rainfall.
E	
EIS	Environmental Impact Statement.
EIQ	Environmental Impact Quotient.
EPA	U.S. Environmental Protection Agency.
EPSPS	An enzyme; 5-enolpyruvylshikimate-3-phosphate synthase.
ESA	Endangered Species Act.
EUP	End Use Product.
Event	See Transformation Event.
Expression	The means by which a gene’s information stored in DNA (or RNA in some viruses) is turned into biochemical information such as RNA or protein.
F	
FAS	Foreign Agricultural Service.
FDA	Food and Drug Administration.
Feral	An animal or plant that has escaped from domestication and returned, partly or wholly, to a wild state.
FFDCA	Federal Food, Drug, and Cosmetic Act.

FGI	Forage Genetics International.
FIFRA	Federal Insecticide, Fungicide and Rodenticide Act.
Foundation seed	Seed of a particular plant variety that is produced from breeder seed and is then planted to produce certified seed used for commercial production. (See Breeder Seed and Certified Seed.)
G	
GE	See Genetically Engineered.
Gene	The basic unit of heredity transmitted from generation to generation during sexual or asexual reproduction; an ordered sequence of nucleotide bases comprising a segment of DNA. A gene contains the sequence of DNA that encodes an individual RNA or protein.
Gene flow	The spread of genes from one population to another by the movement of individuals, pollen, seeds, or spores.
Gene insertion	The incorporation of one or more copies of a gene into a chromosome.
Gene product	A RNA or a protein (e.g. an enzyme), the production of which is directed by the corresponding gene.
Genetic engineering	Genetic engineering refers to the process in which one or more genes and other genetic elements from one or more organism(s) are inserted into the genetic material of a second organism using recombinant DNA techniques.
Genetically engineered (GE)	Modified in genotype and, hence, phenotype using recombinant DNA techniques.
GE organism	Genetically engineered organisms. (See Genetically Engineered.)
GE plant	Genetically engineered plant. (See Genetically Engineered.)
GENEEC	Generic Estimated Exposure Concentration.
Genome	All of the hereditary material in a cell including DNA present in the cell nucleus, as well as in other locations such as plant chloroplasts and mitochondria.
Genotype	The total genetic makeup that an individual receives from its parents.
GIS	Geographic information system.

GRAS	Generally recognized as safe.
GT	Glyphosate tolerant.
H	
Haylage	Alfalfa baled at a higher moisture content than dry hay.
Herbicide	A chemical that kills plants.
Herbicide resistance	The ability of a plant to remain relatively unaffected by the application of what would otherwise be a highly damaging dose of an herbicide.
Human environment	According to the Council on Environmental Quality, the term human environment "shall be interpreted comprehensively to include the natural and physical environment and the relationship of people with that environment." 40 CFR § 1508.14
Hybrid	The offspring of two genetically dissimilar organisms.
Hybridization	When two species interbreed to form hybrid offspring.
I	
Interfertile	Two plants or groups of plants capable of interbreeding and producing offspring.
Interseed	Seeding a crop after a crop has already been established.
Interspecific	Arising or occurring between species.
Intraspecific	Arising or occurring within the same species.
Introgression	The introduction of genes from one species into the gene pool of another via sexual crossing. The process begins with hybridization between the two species, followed by repeated backcrossing to one of the parent species.
IPA	Isopropylamine.
IPCC	Intergovernmental Panel on Climate Change.
Isopropylamine	An organic amine. Used in glyphosate herbicides.

	K
kg	Kilogram.
	L
LOC	Level of concern.
	M
Meristem	A tissue in plants consisting of undifferentiated cells (meristematic cells) and found in zones of the plant where growth can take place - the roots and shoots.
Microorganism	An organism that is microscopic (too small to be seen by the human eye).
MJD	Multi-jurisdictional Database.
mg	Milligram.
MOU	Memorandum of Understanding.
Multiparous	Animals that have given birth more than two or more times.
	N
NAFA	National Alfalfa and Forage Alliance.
NASS	National Agricultural Statistics Service.
NEPA	The National Environmental Policy Act of 1969 and subsequent amendments.
NOI	Notice of Intent.
Non-dormant varieties	Alfalfa varieties that grow through the winter.
Nontarget organism	Organisms that are not the target of a pesticide.
NOP	National Organic Program.
NRCS	Natural Resources Conservation Service.

O

OMRI	Organic Materials Review Institute.
OSTP	Office of Science and Technology Policy.
Outcrossing	The tendency of a plant species to produce offspring that result from the mating of two different individual plants. (See Self-pollinated.)
Ozonation	A water purification and disinfection process.

P

Perennial	Perennials are plant species that live more than two years. They may die in the winter, but grow back from their root-stock the following spring.
Permits	An application to BRS for the introduction of GE organisms that pose a plant pest risk, including plants, insects, or microbes.
Pesticide	A chemical that kills pests. These chemicals include herbicides and insecticides.
Plant pest	Any living stage of any of the following that can directly or indirectly injure, cause damage to, or cause disease in any plant or plant product: protozoan, nonhuman animal, parasitic plant, bacterium, fungus, virus or viroid, infectious agent or other pathogen, or any article similar to or allied with any of the articles specified in the preceding subparagraphs. (7 U.S.C. 7702(14)).
PNW	Pacific Northwest.
POEA	Polyethoxylated tallowamine; a surfactant that may be added to the herbicide formulations to increase leaf penetration.
Post-emergent	Used or occurring in the stage between the emergence of a seedling and the maturity of the crop plant.
PPA	Plant Protection Act.
Pre-plant	Occurring or used before planting a crop.
Pre-emergent	Used or occurring before emergence of seedlings above the ground.

R

Recombinant DNA	DNA, including DNA from different organisms, that has been cut apart and recombined using enzymes.
RED	Reregistration Eligibility Decision.
Regulated article	Subject to APHIS regulation under 7 CFR part 340.
RfD	Reference Dose.
Risk assessment	A scientifically based process consisting of the following steps: (i) hazard identification; (ii) hazard characterization; (iii) exposure assessment; and (iv) risk characterization.
Rotation	In crop production, the cycle of crops grown in successive years in the same field.
RQ	Risk quotient.

S

Secondary seedling	Seedlings that are not planted directly by the farmer but rather sprout unintentionally.
Seedbank	Natural storage of seeds, often dormant, within the soil.
Self-pollinate	The tendency of a plant species to produce offspring that result from a flower pollinating itself. (See Outcrossing.)
Shikimate pathway	Biochemical pathway in plants that produces aromatic amino acids.
Soil tilth	A measure of the health of soil. Good tilth is a term referring to soil that has the proper structure and nutrients to grow healthy crops.
Subchronic toxicity studies	Subchronic toxicity studies are those that study the effects on a small percentage of a subject's life span.

T

T&E	Threatened and Endangered Species.
Trait	A characteristic of an organism that manifests itself in the phenotype. Traits may be the result of a single gene or may be polygenic, resulting from the simultaneous expression of more than one gene.

Transformation	The uptake and integration of DNA in a cell's genome, in which the introduced DNA is intended to change the phenotype of the recipient organism in a predictable manner.
Transgene	A foreign gene that is inserted into the genome of a cell via recombinant DNA techniques.
TSCA	Toxic Substances Control Act.
U	
U.S.C.	United States Code.
USGS	United States Geological Survey.
V	
Vector	The agent, such as a plasmid, used by researchers to carry new genes into cells.
Volunteer	Plants resulting from crop seed that escapes harvest and remains in the field until subsequent seasons, where it germinates along with the succeeding crop.
W	
Weediness	The ability of a plant to colonize a disturbed habitat and compete with cultivated species.
Winterhardy	Those plants that are able to grow during the winter, or at least remain healthy and dormant.

Appendix F. Index

A

Alfalfa

Acreage, 6, 7, 13, 17, 34, 43, 48, 51, 61, 62, 67, 68, 79, 85, 86, 99, 114, 158, 175, 176, 179, 182, 184, 188, G-2, G-3, G-6, G-17, G-32, G-35, J-8, J-23-24, K-6, K-21, K-34-35, N-10-11, N-18, O-2, O-9, O-11-12, O-16, Q-5, Q-35, Q-38-40, Q-54, S-4, S-6, S-12, S-18-24, S-31, S-43, U-9, V-6, V-9-11, V-17-18, V-29, V-31, V-33, V-46-47, V-68-69

Adaptation, 18, 78, 79, 85-86, V-25, V-28

Conventional Alfalfa, xxii, 6-9, 36, 49, 62, 67, 73, 75, 102, 114, 116, 124-132, 136-138, 142, 144, 146, 153, 160, 162, 165-168, 182, 191-192, 197-198, B-2, G-2, G-3, G-7-8, G-10, G-19, G-21, G-32, G-35, I-2, J-4, J-22-23, J-29, J-53, J-54, K-3, K-6-7, K-10-16, K-21, K-32, O-7, O-10-12, P-6-7, Q-2, Q-5-8, Q-43, Q-55, Q-68, R-15, S-2, S-5, S-7, S-12-17, S-23-36, T-2, U-2, U-5-6, U-8, U-12, V-4, V-9-10, V-21-22, V-21, V-31-32, V-35-38, V-49, V-66-68, V-71-74, V-75, V-79-80, V-82, V-84

Costs, xxii, xxiii, 6, 35, 36, 41, 42, 43, 44, 45, 46, 56, 59, 62, 70, 95, 129, 131, 132, 135, 136, 137, 138, 139, 140, 143, 144, 145, 146, 148, 149, 150, 161, 171, 183, 184, 188, 191, 195, K-2-3, S-28, T-2-6, T-13, T-16-19, T-23

Exported alfalfa, 58, 83, 85, G-26, R-6, V-15, V-17, V-47

Feral alfalfa, 19, 102, 104, 106, 108, B-3, G-21, G-55, H-2-4, H-6, H-8, H-10, H-15, H-20, H-62, I-2, I-4-5, I-13, J-5, J-30, U-4, V-2, V-4, V-26, V-28, V-35, V-51-53, V-59, V-61-65, V-72, V-76, V-83, V-85-90

For forage, 17, 19, 34, 44, 51, 52, 67, 69, 85, 110-111, 113, 121, 144, 145, 147, 149, 152, B-2, G-2, G-6, G-1-, G-17, G-19, G-22, G-27-28, G-47-49, H-8-9, I-4, J-4-5, J-36, K-2-3, K-6, K-13-15, K-20-21, K-34-36, N-4, N-10, O-2-3, O-7, O-10-13, O-16, Q-2, Q-5, Q-8, Q-24-28, Q-30, Q-32, Q-38-39, Q-56, Q-65, Q-70-73, R-7-8, R-12, R-15-16, S-8, S-11, S-13, S-16, S-18, S-23-28, S-32-35, T-3, T-17-18, U-4-7, U-9-11, V-2, V-5-9, V-11-12, V-15, V-17, V-21-24, V-28-38, V-45-49, V-51-52, V-58-60, V-66-78, V-84-85, V-89

A, continued.

Genetics, xxiii, 94, 111 (see also Gene Flow)

Glyphosate-tolerant alfalfa, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 13, 15, 18, 22, 33, 64, 66, 72, 75, 95, 116, 138, 178, 194, 197, B-2, B-3-4, G-4, G-10, G-18-19, G-32, I-4-5, J-2, J-3, J-4, J-5, J-7, J-19-20, J-26-27, J-29-30, J-32-36, J-43, J-53-54, K-2-4, K-10, K-12-16, K-18-21, K-25-28, K-33, K-35, M-2-7, M-11, M-24-25, M-27, M-29, M-32, M-35, N-2, N-4-11, N-13, N-18-25, N-45, N-58, N-62, N-70, N-80, N-109, N-113, O-6-12, O-16, Q-2-8, Q-14-17, Q-23, Q-35, Q-39, Q-43, Q-46-47, Q-49, Q-52, Q-54-57, Q-60, Q-62-70, Q-73, Q-74, Q-91, R-2-3, R-9-13, R-15-17, R-22, S-2-7, S-14-17, S-24-37, S-43, T-2-4, T-6, T-14-19, U-2, U-5-12

As human food, 3, 21, 33, 41, 67, 68, 99, 103, 107, 119, 151, G-6-7, J-4, N-4, P-5, Q-2, Q-4-5, Q-8, Q-67

Organic alfalfa, xxiii, 5, 6, 7, 14, 34, 48, 49, 52, 53, 54, 75, 85, 87, 137, 138, 139, 140, 141, 143, 144, 145, 146, 150, 151, 186, G-32, J-2, J-30, J-53-54, Q-2, S-2-4, S-7, S-11-14, S-16-17, S-23-28, S-31, S-33-36, T-18, V-10, V-17, V-21, V-33-34, V-48, V-51, V-78-79, V-95

Quality, 6, 8, 10, 18-19, 26, 35, 40-45, 48, 51-52, 54-56, 61, 64, 69-70, 73, 79, 83, 91, 93, 105-106, 109, 117, 129-132, 135, 136, 143-146, 149, 150, 163-165, 170-171, 181, 183-185, 187, 192-193, 196-197, 199, B-3-4, G-4, G-6, G-10, G-12, G-22, G-36, G-46-47, G-55-56, K-2, K-10-12, K-14-15, K-17-20, K-22, K-26, K-35, O-2-3, O-10-11, Q-8, Q-24-35, Q-65-66, S-4-5, S-9-10, S-12, S-14,, S-16-17, S-24-29, S-31-35, T-2, T-4, T-17-19, U-5-6, U-9-10, V-2-3, V-9, V-15, V-17, V-21-22, V-25, V-28-33, V-36-40, V-45-46, V-50, V-52, V-54, V-61, V-63, V-64, V-68, V-71, V-73-80, V-84, V-101

Reproduction, 19, 100, 117, Q-22-23

Appendix G. Effects of Glyphosate-Resistant Weeds in Agricultural Systems

Effects of Glyphosate-Resistant Weeds in Agricultural Systems

Executive Summary

Alfalfa is grown for forage, grazing, seed production (forage and sprouts), human consumption, and honey production. The most acreage is for dry hay forage. In 2005, 22,439,000 acres of dry hay alfalfa was harvested and 204,380 (0.9%) of those acres were certified organic. In addition to mechanical and cultivation techniques, conventional farming allows the use of 16 different herbicides to control weeds in alfalfa. Organic farming does not allow synthetic pesticides or the use of crop varieties produced through genetic engineering. Glyphosate-tolerant (GT) alfalfa allows for the application of glyphosate directly onto growing plants, which provides increased options for weed control over conventional and organic systems. GT alfalfa allows for flexibility in timing of glyphosate application to control weeds. In the two years that GT alfalfa seed was on the market ~200,000 acres were planted in 1,552 counties in 48 states.

Alfalfa Growing Regions

The seven growing regions in the United States have varying optimal alfalfa varieties and farming practices, such as frequency of cutting, companion cropping, and irrigation. California, South Dakota, Idaho, Nebraska, Montana, and Wisconsin are the top six alfalfa hay producing states (in 2007). South Dakota, Montana, Wisconsin, and North Dakota, have the largest acreage of alfalfa hay. California's acreage is highly productive.

Crop Rotations

Crop rotation options may be different between conventional and GT farming systems. Many of the non-glyphosate herbicides have follow-up planting restrictions that limit crop rotation choices in conventional farming. Farmers using GT cropping systems are advised to include some years of non-GT crops in rotation, so there may be limitations in the use of other GT crops if GT alfalfa is used in a rotation plan.

Alfalfa Stand Removal

Glyphosate is the primary tool used to remove conventional alfalfa stands. Use of herbicides other than glyphosate for removal of GT alfalfa is a major difference between GT alfalfa and conventional alfalfa. Non-glyphosate herbicides and tillage are recommended for effective GT alfalfa stand removal.

Volunteer Alfalfa

Farmers are not able to use glyphosate to control volunteer GT alfalfa in other GT crops. However, 11 other herbicides and mixtures of those herbicides are available to control volunteer GT alfalfa. These are the same herbicides that are used to control non-GT alfalfa with the exception that glyphosate can be used to control non-GT alfalfa.

Weeds in Alfalfa

Weeds are controlled in conventional alfalfa with chemicals (herbicides), cultural methods (rotation, companion crops, monitoring), and mechanical methods (tillage). The cultural and mechanical methods are permitted for organic farmers. GT systems allow for the use of one additional herbicide, glyphosate. Weeds are undesirable because they compete with crops, leading to lower yields, can lower the nutritional value of crops, can be poisonous or unpalatable to livestock, can cause off flavors in milk, and can cause trouble with bailing. At least 129 different weed species are identified as minor or major problems in alfalfa. Out of 14 new glyphosate resistant weeds found since 1998, eight are known to be weeds in alfalfa. Out of at least 21 weeds that have natural resistance to glyphosate, ten are known to be a problem in alfalfa. These 18 weeds that are both resistant to glyphosate and traditionally listed as problems in alfalfa include: common ragweed, horseweed, Italian ryegrass, Johnsongrass, Palmer Amaranth, buckhorn plantain, goosegrass, junglerice, bermudagrass, burning nettle, cheeseweed, common lambsquarters, field bindweed, filaree, large crabgrass, morningglory, nutsedge, and purslane. Although the composition of weed shifts is based on the local seedbank, these 18 weeds are candidates for becoming more prevalent than glyphosate-resistant sensitive weeds in rotations that include GT alfalfa.

Glyphosate Resistant Weed Distribution

Nineteen states and over two million acres of cropland contain new glyphosate resistant weeds. The heaviest infestation is in the Southeast and Midwest. Overlap with the major alfalfa producing states in the Intermountain regions (Washington, Oregon, Idaho, Montana, Wyoming, Colorado, Utah, Nevada, and parts of California) seems to be minimal at this point. However, given that there is overlap between glyphosate resistant weed locations and alfalfa hay acreage there is potential for rapid shifts of glyphosate resistant weeds into GT alfalfa fields if GT alfalfa were to be widely adopted. California is a concern because glyphosate resistant weeds are present and alfalfa is a major crop in California.

1.0 Introduction

The scope of this report covers how glyphosate-tolerant (GT) alfalfa could impact weed dynamics in agricultural systems. Gene flow from GT alfalfa is covered in another technical report in this series (Appendix J). In this report, different types of alfalfa crops and cropping systems are described. Regional differences in alfalfa farming are summarized and discussed within the context of weed management. Glyphosate resistant weeds and the potential risks from volunteer GT alfalfa are also discussed. This report is limited to weed dynamics in agricultural systems. Potential effects of farming with GT alfalfa on ecosystems is discussed in other technical reports. This report is limited to practices involving weed management and does not include discussion of control of diseases, insects, nematodes, and vertebrate pests and management of field fertility and soil conservation.

Weed management is an important aspect of alfalfa production. Some of the negative effects of weeds include the following (Canevari et al., 2007; Canevari et al., 2006; Van Deynze et al., 2004; Loux et al., 2007; Miller et al., 2006; Orloff et al. 1997):

- Competition with weeds can reduce yield and cause thinning in the stand.
- Weeds can lower the nutritional quality of alfalfa hay because many weeds are lower in protein (50 percent less protein than alfalfa) and higher in fiber compared to alfalfa.
- Poisonous weeds containing toxic alkaloids (e.g., common groundsel, fiddleneck, yellow starthistle, and poison hemlock) can make alfalfa hay unmarketable.
- Under some conditions weeds can accumulate toxic nitrate concentrations (e.g., lambsquarters, kochia, and pigweed).
- Some weeds with a spiny texture can cause mouth and throat ulcerations in livestock (e.g., foxtail, wild barley, cheatgrass, and bristleglass).
- Weeds that are unpalatable to livestock result in less feeding and, therefore, less productivity (either beef or milk).
- Some weeds can contribute to off flavors in milk (wild celery, Mexican tea, creeping swinegrass, and mustards).
- Weeds that contain higher moisture content than alfalfa (dandelion) can cause bail problems such as mold, off-color hay, and high bale temperatures, which are a fire hazard.

Without weeds, alfalfa can grow at a density of about 12 plants per square foot. Heavily infested stands can have less than one alfalfa plant per square foot (Canevari et al., 2007). In California, if weeds are not effectively controlled weeds can represent up to 76 percent of the first cutting yields (Gianessi et al, 2002). The limiting factor for weed control in alfalfa is that, by the time alfalfa reaches the stage of growth that is tolerant to herbicides, weeds are also beyond their susceptible stage (Gianessi et al., 2002). Glyphosate-tolerant alfalfa was developed so that the broad spectrum herbicide, glyphosate, could be applied directly to alfalfa fields to control weeds. The glyphosate-tolerant (GT) trait was introduced through genetic engineering. Although glyphosate-tolerance has arisen naturally in some plants due to decades of glyphosate use, so far, all crops with glyphosate-tolerance have had the trait introduced through genetic engineering.

1.1 Methodology

A literature search was designed to identify peer review articles and grey literature (e.g., government reports, State Agricultural Extension Office publications) on weeds in alfalfa (Appendix G-2 of this technical report). Several DIALOG databases were searched. Google, Google Scholar, Scirus, and Yahoo search engines supplemented the DIALOG search. Calculations for percentages of harvest were done with Microsoft Excel. Alfalfa harvest statistics were obtained from USDA's National Agricultural Statistics Service (<http://www.nass.usda.gov/index.asp>). In addition, USDA's Economics, Statistics and Market Information System (ESMIS), which is a collaborative project between Albert R. Mann Library at Cornell University and USDA, provided information on alfalfa harvesting (<http://usda.mannlib.cornell.edu/MannUsda/homepage.do>). USDA's Agricultural Marketing Service also provided information on harvests (<http://www.ams.usda.gov>). The common and scientific names for weeds (Appendix G-3 of this technical report) were found in the USDA Plants database (<http://plants.usda.gov/java/invasiveOne>).

2.0 Alfalfa Cropping Systems

This chapter discusses how alfalfa is used, the farming practices for growing alfalfa, and the alfalfa growing regions in the United States.

2.1 Alfalfa Uses

Alfalfa is grown for seed production, human food, honey, grazing, and forage. Forage comprises the largest acreage for alfalfa stands. In 2007, 72.5 million tons of dry hay alfalfa was produced from 21.6 million acres harvested (www.nass.usda.gov).

2.1.1 Forage

Alfalfa is considered the “Queen of Forages” because of its high nutritional content when fed to cattle and horse livestock (Putnam et al., 2001). Due to climate and other differences, farming practices differ regionally. However, some farming characteristics are shared among growing regions. Alfalfa stands have two growing phases, establishment of seedlings (first year) and established (two to eight years). Weed management differs for each phase (Orloff et al., 1997). During the seedling establishment phase, companion or nursery crops, such as oats, wheat, and barley can be used to help shelter the alfalfa seedlings, help prevent soil erosion, and suppress weeds because they germinate and grow faster than alfalfa (Canevari et al, 2007). Well established alfalfa that is not thinning has fewer issues with weeds because established alfalfa is a good competitor. Alfalfa can be harvested (mowed) every 30 to 50 days depending on growth conditions in the region, local weather patterns, and alfalfa variety. In most of the growing regions, alfalfa is only cut three to four times a year, but in the Southwestern U.S. growers can cut up to 10 or 11 times per year (Putnam et al., 2001). To determine when to harvest, farmers balance yield and nutritional content. Yield increases as plants grow and peaks at 100% bloom, but nutritional content is highest in young vegetative plants and decreases until full flower. There is no optimal harvest schedule, because farmers make different decisions based on changing market demand. Farmers may choose to harvest between late bud stage and full bloom, however, alfalfa hay production experts recommend cutting alfalfa for hay at 10% bloom, as this stage provides the most valuable and nutritious forage (e.g., Sheaffer et al. 2000). The highest quality hay (bud stage) is generally used for active dairy cows. Whereas hay that is lower in protein and higher in fiber, is fed to beef cattle, horses, heifers (too young to milk) and non-lactating dairy cows (Ball et al., no year). Alfalfa for livestock feed can be stored in a variety of forms:

- Hay - dry baled at 18-20% moisture
- Haylage - round bale silage, baled at 50-60% moisture, wrapped in plastic
- Silage - chopped and blown into a silo or a truck

2.1.2 *Grazing*

Grazing is sometimes used as an alternative to harvesting alfalfa. Grazing allows for high nutritional gains per animal, but the risks include animal losses due to bloating and difficulties in alfalfa stand maintenance if continuous grazing is present. Farmers may choose grazing for dormant-season alfalfa stubble, a substitute for early or late season cutting, and rotational grazing during the growing season. It is strongly recommended that animals not graze before flowering begins. Alfalfa root carbohydrate reserves may not be sufficient if early grazing is permitted and the potential for bloat decreases with flowering (Orloff et al., 1997).

2.1.3 *Seed Production (Hay and Sprouts)*

Alfalfa is also consumed by humans (e.g., sprouts, dietary supplements, and herbal teas). Sprouts have been the source of several foodborne outbreaks due to bacterial contamination (FDA 1999). Epidemiological investigations suggest that seeds are the likely source in most, if not all, sprout-associated illness outbreaks. Seed grown for sprouts have more stringent restrictions for chemical applications during growing since the chemicals must be evaluated as food residues. Sources of animal waste in fields, such as grazing areas and irrigation water, must also be controlled to reduce the likelihood of pathogens from animal waste coming into to contact with seeds. For these reasons, sprout seed and hay seed are usually grown separately (FDA 1999).

FDA considers GT alfalfa not materially different from conventional alfalfa; therefore it is permitted for human consumption (FDA 2004). However, Monsanto does not allow GT alfalfa to be planted for sprouts (Hubbard 2008). If GT alfalfa was present in human food, it would not be considered adulterated and would not need to be removed from the market.

2.1.4 *Honey*

Alfalfa and clover are common nectar sources for honey bee hives. Although alfalfa is not specifically grown for bees, both managed and wild bee hives are often associated with alfalfa fields (Hammon et al., 2007).

2.2 **Alfalfa Farming Practices**

Alfalfa farming practices are broken into three categories, organic, conventional, and glyphosate-tolerant alfalfa. Only aspects of farming related to weed control are discussed. Practices for controlling disease, insects, nematodes, and vertebrate pests and management of field fertility and soil conservation are not discussed.

2.2.1 *Organic Farming*

For this report, organic production is only those cropping systems that fall under the USDA National Organic Program (NOP) definition of organic farming and are certified organic production systems. In organic systems, the use of synthetic pesticides, fertilizers, and genetically engineered crops is strictly limited. NOP publishes a list of approved substances for organic farming inputs (<http://www.ams.usda.gov/AMSV1.0>).

GT alfalfa is not approved for use in organic systems because it is genetically engineered and because glyphosate application is not permitted in organic systems.

In organic systems, where herbicides are not permitted, alfalfa is tilled and allowed to sit for seven to ten days. Two or more disking passes may be necessary if weed germination is observed. The field should also be treated with nutrients, such as compost and boron, and left for a week to check for further weed germination. Planting can occur once weed growth potential is minimized (Guerena and Sullivan 2003). Manure fertilizer should be composted to kill weed seeds (Canevari et al., 2007).

2.2.2 Conventional Farming

Conventional farming includes any farming system where synthetic pesticides or fertilizers are used. The definition of conventional farming usually includes the use of genetically engineered crops, but genetically engineered GT alfalfa is considered separately for this report (Harker et al., 2005). Conventional farming covers a broad scope of farming practices, ranging from farmers who only occasionally use synthetic pesticides to those farmers whose harvest depends on regular pesticide and fertilizer inputs. The 16 herbicides that may be used in conventional farming are summarized in table G-1 (based on OMAFRA 2008; Canevari et al., 2007; Rogan and Fitzpatrick 2004; Loux et al., 2007).

Table G-1. Herbicides Used in Conventional Alfalfa Farming

Herbicide (Brand)	Stand Stage	Weed	Notes
2,4-DB (Butyrac, Butoxone)	1-4 trifoliolate or established stands	Prickly lettuce Annual sowthistle Mustards Curly dock	• No harvesting or grazing allowed for 60 days following treatment
Benefin (Balan)	Before seeding	Annual grasses Broadleaf	• Not for use on soils high in organic matter
Bromoxynil (Buctril)	2-4 trifoliolate	Coastal fiddleneck Mustard0s Common groundsel Annual sowthistle	• Often tank mixed with other herbicides
Clethodim (Prism, Select)	2-4 trifoliolate or established stands	Summer grasses Yellow foxtail Green foxtail Barnyardgrass Bermudagrass Johnsongrass Goosegrass Volunteer cereals	• Well established perennials require multiple applications • Allow 15 days between application and grazing, feeding, or harvesting of alfalfa
Diuron (Karmex, Direx)	Established stands	Winter annuals Broadleaf Some grasses	• Persists in soil for one year, so cannot be used in last year of stand
EPTC (Eptam)	Established stands	Summer grasses Nutsedge	• Applied before germination • Controls for 30 to 45 days so repeated applications may be necessary

Hexazinone (Velpar)	6 inches of root growth in new stands or established stands	Broadleaf Grasses Common groundsel Chickweed miners Lettuce annual Bluegrass dandelion Buckhorn plantain Speedwell	• Many crops cannot be planted for 18 months without yield damage
Imazamox (Raptor)	2-4 trifoliolate or established stands	Winter annual Grasses Broadleaf	• Preharvest interval is 20 days
Imazethapyr (Pursuit)	2-4 trifoliolate or established stands	Winter annuals Mustards Shepherd's purse Creeping swinecress Chickweed	• Follow-up planting restrictions range from 4 to 40 months
Metribuzin (Sencor)	Established stands	Lamb's-quarters Wild mustard Redroot pigweed Common ragweed Shepherd's-purse Lady's-thumb Velvetleaf Jimsonweed Prostrate pigweed Russian thistle Yellow wood-sorrel Prickly mallow Chickweed Cocklebur Carpetweed Dandelion seedlings Barnyard grass Crab grass Foxtail Fall panicum Witch grass Johnson grass Cheat grass	• No grazing or harvesting allowed for 28 days following application
Norfluzon (Solicam)	Established stands	Broadleaf Grasses Nutsedge	• Cannot be applied within 28 days of harvest • Does not control emerged weeds • 24 month rotation interval
Paraquat (Gramoxone Inteon)	3, 6, or 9 trifoliolate; established stands	Broad spectrum	• Rescue treatment when weeds form a canopy over alfalfa • No harvest or grazing until 60 days after application • Often used in the last year of the stand
Pronamide (Kerb)	First trifoliolate leaf stage	Perennial grasses Quack grass Annual grasses Volunteer cereals Common chickweed	• No grazing or harvesting allowed for 120 days following application
Sethoxydim (Poast)	2-4 trifoliolate or established stands	Summer grasses Yellow foxtail Green foxtail Barnyardgrass Bermudagrass Johnsongrass Goosegrass	• Well established perennials require multiple applications
Terbacil (Sinbar)	Established stands	Barnyard grass Bluegrass Crab grass Foxtail Chickweed Cheat grass Perennial rye grass Wild barley Mustard Prickly lettuce Stinkweed Annual sow-thistle Henbit Lamb's-quarters Pigweed	• Can not plant any other crop for 2 years after Sinbar application

		Purslane Ragweed Partial control of: Quack grass Horsenettle Vetch Yellow nut sedge	
Trifluralin (Treflan/TR-10)	Established stands	Summer grasses	<ul style="list-style-type: none"> • Applied before germination • Rainfall or sprinkler irrigation is required within 3 days after irrigation to incorporate the herbicide • Controls dodder before germination

2.2.3 GT Farming

GT alfalfa can be integrated into conventional farming practices. Farming GT alfalfa is mostly the same as farming conventional alfalfa, with two important exceptions. Weeds can be controlled by the application of glyphosate directly on top of growing alfalfa and, when alfalfa stands reach the end of their life cycle (typically after 3-8 years depending on growing region), glyphosate cannot be used to kill the stand to prepare for another rotation (Miller et al., 2006). In GT alfalfa, herbicides other than glyphosate combined with tillage are required to obtain 100 percent removal. Several of the recommended GT alfalfa stand removal herbicides result in restrictions regarding what crops can be planted next, so careful crop rotation plans are necessary when using GT alfalfa. Stand removal is discussed in the technical report *Effects of Changes in Farming Practices on Water, Soil and Air Due to Use of Glyphosate-Tolerant Alfalfa* (appendix J).

Another important difference to some farmers is that non-GT crops cannot be used as companion crops for GT alfalfa. For farmers that plant pure alfalfa stands this difference does not matter. For farmers that traditionally use companion crops, this difference is important. Companion crops can increase overall forage yield but decrease hay quality (McCordick et al., 2008).

2.2.4 Crop Rotation in Alfalfa

For weed, insect, and disease management, it is recommended that alfalfa be used in rotation with other crops. It is also advised to rotate alfalfa because mature alfalfa produces medicarpin, which is auto toxic to seedling alfalfa (Guerena and Sullivan 2003). This autotoxicity is the primary problem for alfalfa seeded after alfalfa (Jennings, no year). Table G-2 presents rotation recommendations for control of several common alfalfa pests.

Table G-2. Recommended Rotations for Pest Reduction (Goodell 2006)

Pest	Recommended Rotation
Root knot nematode	1 year rotation with cotton
Stem nematode	3-4 year rotation with small grains, beans, cotton, corn, sorghum, lettuce, carrots, tomatoes, or forage grasses.*
Diseases: Bacterial wilt Anthracnose Spring blackstem Common leafspot Stagonospora	3-4 year rotation with small grains, beans, corn, sorghum, forage grasses.*
Winter weeds	A minimum of 1 year (preferably longer) in crops such as small grains, wheat, oats, winter forage grasses that allow the use of selective herbicides that are not registered in alfalfa.
Summer weeds	A minimum of 1 year (preferably longer) in crops such as small grains, beans, cotton, corn, sorghum, summer forage grasses that allow the use of selective herbicides that are not registered in alfalfa.
Dodder	At least 2 years with cotton or other nonhost crops such as small grains, beans, corn, sorghum, or forage grasses. Avoid rotations with crops such as tomatoes, onions, and carrots that also serve as a host for this weed.
Nutsedge	Two year rotation with corn or sorghum rotation that includes application of herbicide to control nutsedge.

* Three to four-year rotations give satisfactory results. A rotation for fewer years will provide minimal suppression.

Herbicides that can be used to remove GT alfalfa have rotation restrictions. For example, following clopyralid (Curtail® or Stinger®), pea, lentil, potato, and dry bean cannot be planted for 18 months. Picloram (Tordon®) can only be followed by grasses for the year after application. Sunflower, dry bean, and potato should not be planted for several years following picloram (Miller et al., 2006). Dicamba (Banvel®) should not be used prior to soybean and is also limited seasonally in California (Dillehay and Curran 2006). Because of these restrictions, alfalfa stand removal and rotation schedules should be closely coordinated. Non-glyphosate herbicides are available to manage alfalfa volunteers in wheat, oats, barley, sugar beet, and corn. Therefore rotations from GT alfalfa to those crops should be similar to rotations with non-GT alfalfa (Rogan and Fitzpatrick 2004).

Smother crops planted before alfalfa can suppress weeds. For example, sorghum-sudangrass hybrid or foxtail millet both suppressed weeds and enhanced subsequent alfalfa establishment (Forney et al., 1985).

No-till GT corn can be planted directly into alfalfa. In a study comparing no-till GT corn planted into cut or uncut alfalfa and various herbicide applications to control the alfalfa, corn yield was 13% higher following herbicide applications to uncut alfalfa. Application of glyphosate and dicamba at planting resulted in the greatest corn yield. Given that alfalfa is also a valuable crop, whether the corn yield gain is worth the loss of an alfalfa harvest should be weighed (Glenn and Meyers 2006).

2.3 Alfalfa Growing Regions

Figure G-1: Alfalfa growing regions (Rogan and Fitzpatrick 2004)

The Association of Official Seed Certifying Agencies, National Alfalfa and Miscellaneous Legumes Variety Review Board and USDA Plant Variety Protection Office recognizes seven growing regions in the United States, Moderately Winterhardy Intermountain, Winterhardy Intermountain, Southeast, Great Plains, North Central, East Central, and Southeast (figure G-1) (<http://www.aosca.org/VarietyReviewBoards/Alfalfa.html>). In addition, the Pacific Northwest, which includes Moderately Winterhardy Intermountain and Winterhardy Intermountain, is also sometimes recognized as a distinct growing region.

Table G-3 and table G-4 summarize the winter survival and fall dormancy ratings for alfalfa varieties. The National Alfalfa & Forage Alliance (NAFA) publishes a list of varieties and their winter survival ratings, fall dormancy ratings, and susceptibility to 17 different crop stresses (e.g., diseases, insects, grazing). The list is updated yearly and the 2007/2008 version lists 242 varieties of alfalfa (NAFA 2008). When selecting a variety, farmers consider yield, stand persistence, dormancy, pest and disease resistance, herbicide resistance, hay quality, price, seed certification, and other factors that may be specific to their farming situation (Orloff et al., 1997).

Table G-3. Winter Survival Ratings

Category	Check Variety	Score
Superior	ZG 9830	1
Very Good	5262	2
Good	WL325HQ	3
Moderate	G-2852	4
Low	Archer	5
Non Winterhardy	Cuf 101	6

Table G-4. Fall Dormancy Ratings

Check Variety	Rating
Maverick	1
Vernal	2
5246	3
Legend	4
Archer	5
ABI 700	6
Dona Ana	7
Pierce	8
CUF 101	9
UC-1887	10
UC-1465	11

1 is very dormant, 11 is extremely non-dormant

Table G-5 presents the U.S. states in order of percentage of alfalfa harvest (in 2005). For each state, the growing region, the percentage of the total national harvest of all alfalfa are presented for 2002, 2005, and 2007; and the percentage of the national organic certified harvest are presented for 2002 and 2005. In 2005, the most recent USDA organic harvest report, 22,439,000 acres of dry hay alfalfa was harvested and 204,380 (0.9 percent) of those acres were certified organic. The number of acres harvested in a state does not indicate the quantity of the harvest. For example, as shown in table G-5, because of the growing season length, California ranks top in production (in 2007, ~11 percent of the national harvest and ~7 million pounds) and South Dakota ranks second (in 2007, ~6.8 percent of the national harvest and ~4 million pounds) even though South Dakota has ~2 million acres and California has less than 1 million acres of alfalfa. In addition, even though the Northeastern states rank low in the percentage of acres and quantity of harvest, alfalfa is the number one crop for several of those states (NAFA 2007).

Table G-5. Alfalfa Growing Regions and Percentage of Dry Hay Harvest by State

State	Growing Region	Percent of harvest acres			Percent of organic harvest	
		2002	2005	2007	2002	2005
South Dakota	North Central	10.57	10.70	9.86	8.58	6.82
Montana	Winter Hardy Intermountain	6.76	7.80	9.23	3.66	2.60
North Dakota	North Central	6.13	7.35	7.20	11.22	10.09
Wisconsin	North Central	7.32	6.91	7.50	16.34	14.38
Minnesota	North Central	5.59	6.02	4.67	6.40	10.44
Iowa	North Central	5.16	5.57	4.10	6.11	4.50
Nebraska	North Central	5.92	5.57	5.36	2.71	4.01
Idaho	PNW-Intermountain	4.57	5.08	5.12	24.69	24.22
California	Moderate Winter Hardy Intermountain/ Southwest	5.19	4.63	4.88	2.92	6.48
Michigan	East Central	3.56	4.01	3.45	2.07	0.35
Kansas	Great Plains	4.14	3.79	3.92	1.40	0.32
Colorado	Winter Hardy Intermountain	3.40	3.57	4.25	3.45	4.38
Wyoming	Winter Hardy Intermountain	2.16	2.67	3.33	0.19	0.84
Utah	Moderate Winter Hardy Intermountain	2.48	2.41	2.71	0.60	0.45
Ohio	East Central	2.71	2.27	2.16	1.89	0.50
Pennsylvania	East Central	2.96	2.27	2.35	0.96	0.60
Missouri	East Central	1.77	2.01	1.46	0.23	0.58
New York	East Central	2.90	2.01	2.22	1.34	0.16

ND = no data provided by USDA

Other differences in alfalfa farming are revealed by examining the number of farms that grow alfalfa and the number of farms that irrigate. Comparison of California and Wisconsin (table G-6) shows that in California ~97 percent of the farms irrigate, whereas in Wisconsin only 0.5 percent of the farms irrigate. In addition, the average farm size in California is much larger than in Wisconsin. It should be noted that the average farm size calculation is a bit misleading because in California mainly two farm sizes exist, small and very large (4,000 acres). In general, because farm size does not fit a normal distribution, the average farm size does not give a full picture of farm sizes. However average farm size does relay the general trend of farm size in a state. Like any census, these data may not include all alfalfa farms.

Table G-6. Alfalfa Dry Hay Harvest 2007 U.S. Agricultural Census

State	Number of Farms	Acres Harvested	Quantity (pounds) Harvested	Farms Irrigated	Acres Irrigated	% of Acres	% of Pounds	Avg. Acres per Farm

2.4 Summary of Findings

Alfalfa is grown for forage, grazing, seed production (forage and sprouts), human consumption, and honey production. The most acreage is for dry hay forage. Alfalfa is currently grown through conventional farming practices, organic farming, and in glyphosate-tolerant systems. In addition to mechanical and cultivation techniques, conventional farming allows the use of 16 different herbicides to control weeds in alfalfa. Organic farming does not allow synthetic pesticides or the use of crop varieties produced through genetic engineering. GT alfalfa allows for the application of glyphosate directly onto growing plants, which provides increased options for weed control over conventional and organic systems. In 2005, 22,439,000 acres of dry hay alfalfa was harvested and 204,380 of those acres were certified organic.

Crop rotation options may be different between conventional and GT systems. Many of the non-glyphosate herbicides have follow-up planting restrictions that limit crop rotation choices in conventional farming. Farmers using GT cropping systems are advised to include some years of non-GT crops in rotation, so there may be limitations in the use of other GT crops if GT alfalfa is used in a rotation plan.

The seven growing regions in the United States have varying optimal alfalfa varieties and farming practices, such as frequency of cutting, companion cropping, and irrigation. California, South Dakota, Idaho, Nebraska, Montana, and Wisconsin are the top six alfalfa hay producing states (in 2007). South Dakota, Montana, Wisconsin, and North Dakota, have the largest acreage of alfalfa hay. California's acreage is highly productive.

3.0 Glyphosate-Tolerant Alfalfa (Roundup Ready®)

Glyphosate-tolerant (GT)²³ alfalfa was deregulated in 2005 and by 2006, ~80,000 ha (~200,000 acres) were planted in the United States (Beckie and Owen 2007).²⁴ USDA APHIS lists all the counties in the United States where GT alfalfa has been planted (<http://www.aosca.org/VarietyReviewBoardsAlfalfa.html>). GT alfalfa has been planted in 1,552 counties and 48 states. Alaska and Hawaii do not have GT alfalfa. In March of 2007 USDA published notice in the Federal Register that GT alfalfa is a regulated article and GT alfalfa seed sales and plantings were halted. GT alfalfa planted in the 2005 and 2006 growing seasons is still permitted to be harvested, but has court ordered stewardship practices to minimize risk of co-mingling GT and non-GT alfalfa (Hubbard 2008).

3.1 Using GT Alfalfa

Van Deynze et al., (2004) reported that in field trials when Roundup® (glyphosate) was applied during alfalfa stand establishment at the 3 to 4 trifoliolate stage, weeds were controlled and usually no second application was needed. Early applications allowed for late germination of weeds and later applications allowed weeds to compete with alfalfa. For example in the intermountain region applications at the unifoliolate to first trifoliolate stage resulted in invasion by prickly lettuces and henbit and required a second application. In the Southwest annual bluegrass and canarygrass germinated in early December and required a second application of glyphosate for control. The effectiveness of the first application during stand establishment is a function of which weed species are present and their germination period as well as how soon after application the alfalfa canopy covers the soil surface. In California there is period of time in the winter when alfalfa stands are dormant and rain causes winter weeds to germinate.

Recommended application of glyphosate to GT alfalfa is 0.75 to 1.5 pounds acid equivalent per acre (22 to 44 fluid ounces Roundup Weathermax 4.5S® per acre) at the three to five trifoliolate stage during stand establishment and up to five days before harvest in established stands (Dillehay and Curran, 2006). The maximum labeled rate for a single use of glyphosate on GT alfalfa is 1.55 pounds glyphosate acid equivalent per acre.

Alfalfa is polyploid (tetraploid), so small percentages (three to seven percent) of the seedlings do not have the GT trait. This is similar for other genetic traits. If glyphosate is sprayed early enough, plants containing the GT trait will fill in gaps left by dead weeds and non-GT alfalfa that was killed (Van Deynze et al., 2004). Up to six percent injury was observed after the first glyphosate application in a new stand, but was gone by the time of first harvest (McCordick et al., 2008). In GT alfalfa, crop injury from glyphosate application is much less than for other herbicides (Canevari et al, 2007).

GT alfalfa is an option for weed control; however it may not be appropriate in the following situations (Dillehay and Curran, 2006):

²³ "Resistance" and "tolerance" are usually synonyms and are often used interchangeably. In this report "tolerance" is used to indicate crop varieties that are intentionally engineered to withstand glyphosate application. "Resistance" is used to indicate weeds and weed biotypes that can withstand glyphosate application.

²⁴ 2.471 acres = 1 ha = 104 m²

- Alfalfa-grass mixtures and alfalfa seeded with companion/nursery crops
- Fields that have a history of low weed populations
- Fields that are rotated between alfalfa and other GT crop varieties (e.g. Roundup Ready® soybean)

McCordick et al. (2008) tested GT alfalfa in 2004 and 2005 growing seasons in field studies in Michigan. Two seeding regimes were used, clear seeded (only alfalfa seed) and oat companion crop. In both of these seeding regimes glyphosate, imazamox, and untreated conditions were tested. For the oat companion crop stands, clethodim was added to the imazamox treatment to increase control of oat. In the first year (stand establishment), temporary stunting was observed with glyphosate treatment, but it did not affect yield or stand density. Clear seeded alfalfa treated with glyphosate yielded the highest alfalfa dry matter in both years, even though combined forage yield was higher in the oat companion crop. When no herbicide was applied the oat companion crop had lower weed biomass than clear seeded alfalfa.

3.1.1 *Stand Establishment*

Forage alfalfa is planted in the spring and in the early fall in the Southwest and western regions. Currently trifluralin, EPTC, imazethapyr, imazamox, sethoxydim, clethodim, and bromoxynil herbicides are sometimes used during spring stand establishment and could be replaced with glyphosate if GT alfalfa is used. Use of GT alfalfa also allows weed control during late-summer and fall establishment (Rogan and Fitzpatrick 2004).

3.1.2 *Stand Removal*

One of the major differences between conventional alfalfa and GT alfalfa occurs during stand removal. Whereas glyphosate is often used to kill old stands of conventional alfalfa for crop rotations, GT alfalfa has to be removed through other mechanisms. Application of an herbicide (e.g., 2,4-D, dicamba (Banvel®), and clopyralid (Stinger®)) and tillage is effective. In no-till systems 2,4-D and dicamba can be applied together. However dicamba cannot be used before planting soybean (Dillehay and Curran, 2006).

Renz 2007 reported that dicamba and 2,4-D (WeedMaster®) applied at 2 pt/A achieved zero resprouting of alfalfa in the spring following herbicide application. Lower concentrations of WeedMaster resulted in 0.3 to 2.5 percent resprouting. The other herbicides applications (dicamba or 2,4-D only) resulted in 0.5 to 26.5 percent resprouting. In another study, picloram and 2,4-D was more effective than dicamba and 2,4-D (Miller et al., 2006). Combined with plowing, clopyralid, clopyralid plus 2,4-D, dicamba plus 2,4-D, picloram, and picloram plus 2,4-D all controlled alfalfa 100 percent. Plowing alone provided 75 percent control (Miller et al., 2006).

Potential effects of changes in tillage practices due to the use of GT alfalfa are discussed in the technical report *Effects of Changes in Farming Practices on Water, Soil and Air Due to Use of Glyphosate-Tolerant Alfalfa* (appendix K).

Figure G-2 shows Monsanto's guidance for GT alfalfa stand removal (Monsanto 2008).

STAND TAKEOUT AND VOLUNTEER MANAGEMENT	
<p>Crop rotations can be divided into two main groups, alfalfa rotated to: 1) grass crops (e.g. corn and cereal crops); and 2) broadleaf crops. More herbicide alternatives exist for management of volunteer alfalfa in grass crops. The recommended steps for controlling volunteer Roundup Ready Alfalfa are:</p> <p>Diligent Stand Takeout</p> <p>Use appropriate commercially available herbicide treatments alone for reduced tillage systems or in combination with tillage to terminate the Roundup Ready Alfalfa stand. Refer to your regional technical bulletin for specific stand takeout recommendations. NOTE: Roundup agricultural herbicides are not effective for terminating Roundup Ready Alfalfa stands.</p> <p>Start Clean</p> <p>If necessary, utilize tillage and/or additional herbicide application(s) after stand takeout, and before planting of the subsequent rotational crop to manage any newly emerged or surviving alfalfa.</p>	<p>Plan for Success</p> <p>Rotate to crops with known and available mechanical or herbicidal methods for managing volunteer alfalfa, keeping in mind that Roundup agricultural herbicides will not terminate Roundup Ready Alfalfa stands.</p> <ul style="list-style-type: none"> • Rotations to certain broadleaf crops are not advisable if the grower is not willing to implement recommended stand termination practices. • In the event that no known mechanical or herbicidal methods are available to manage volunteer alfalfa in the desired rotational crop, it is suggested that a crop with established volunteer alfalfa management practices be introduced into the rotation. <p>Timely Execution</p> <p>Implement in-crop mechanical or herbicide treatments for managing alfalfa volunteers in a timely manner; that is, before the volunteers become too large to control or begin to compete with the rotational crop.</p>

Figure G-2: Monsanto's guidance for GT alfalfa stand removal (Monsanto 2008)

3.2 Volunteer GT Alfalfa

Crop rotation is the practice of alternating crop species in the same field in different years. Crops are considered volunteer when they grow in a field during a year when they have not been planted intentionally. Volunteer crops are weeds because they compete with the current crop for resources and they may harbor insect and disease pests. For example, volunteer GT cotton in GT soybean can harbor boll weevil. Boll weevil is a serious cotton pest and is monitored aggressively in cotton for eradication. However boll weevil is not monitored in soybean (York, et al., 2004).

Volunteer GT crops have to be controlled through the use of other herbicides. For example GT wheat and canola is best controlled through paraquat and diuron (Rainbolt et al., 2004). Volunteer GT canola needs to be controlled before replanting canola because cultivars with different resistance genes can cross and result in multiple herbicide resistance (Rainbolt et al., 2004).

Herbicides that are used to control alfalfa, including GT alfalfa include (Rogan and Fitzpatrick 2004; Renz 2007; Dillehay and Curran, 2006; Miller et al., 2006):

- 2,4-D
- Clopyralid
- Dicamba
- Dicamba and diflufenzopyr
- Glufosinate
- Primsulfuron-methyl

- Mixtures of dicamba, 2,4-D, and clopyralid
- Picloram
- Picloram and 2,4-D
- Halosulfuron and dicamba
- Acetochlor
- Acetochlor and atrazine
- Acetochlor and atrazine and dicamba
- Atrazine and dicamba
- Clopyralid and flumetsulam

Monsanto demonstrated in their Deregulation Petition that the last five herbicides and mixes on the above list can control volunteer GT alfalfa in corn (Rogan and Fitzpatrick 2004). Clopyralid is effective at controlling volunteer alfalfa in broccoli (Tickes 2002). Clopyralid or 2,4-D provide control of volunteer alfalfa in 33 different crops. Exceptions include potatoes and popcorn (Rogan and Fitzpatrick 2004).

Feral alfalfa (alfalfa not in fields) is discussed in more depth in the technical report *Effects of Glyphosate-tolerant Weeds in Non-agricultural Ecosystems* (appendix H).

3.3 Summary of Findings

GT alfalfa allows for flexibility in timing of glyphosate application to control weeds. In the two years that GT alfalfa seed was on the market ~200,000 acres were planted in 1,552 counties in 48 states.

Glyphosate is the primary tool used to remove conventional alfalfa stands. Use of herbicides other than glyphosate for removal of GT alfalfa is a major difference between GT alfalfa and conventional alfalfa. Non-glyphosate herbicides and tillage are recommended for effective GT alfalfa stand removal.

Farmers are not able to use glyphosate to control volunteer GT alfalfa in other GT crops. However, eleven other herbicides and mixtures of those herbicides are available to control volunteer GT alfalfa. These are the same herbicides that are used to control non-GT alfalfa with the exception that glyphosate can be used to control non-GT alfalfa.

4.0 Weeds in Alfalfa

Although weeds can be a problem in alfalfa, once alfalfa is established, it acts as a suppressor of weeds and is commonly used in rotations for weed reduction. For example, prior rotation in alfalfa can reduce weed densities in sunflower to the same level as herbicide treatment and alfalfa in corn rotations also benefited corn yield and suppressed weeds (Clay and Aguilar 1998). Fields with a history of perennial weed infestation are not well suited for alfalfa (Canevari et al, 2007).

Wilson (1981) tested seven herbicides on dormant alfalfa in Nebraska and found good weed control that resulted in increased protein and total digestible nutrients (except for hexazinone application) compared to untreated control plots. Weeds that were successfully controlled included kochia, downy brome, tansymustard, Russian thistle, and prickly lettuce. Out of 48 weeds in alfalfa listed by the University of California Pest Management Guidelines, five weeds are not controlled by glyphosate: green foxtail, filed bindweed, yellow nutsedge, buckhorn plantain, and burning nettle. There was no data on pepperweeds. Three weeds stand out (field bindweed, yellow nutsedge, and buckhorn plantain) because they are not controlled well by glyphosate or any of the other 16 herbicides evaluated (table VII-3 in Rogan and Fitzpatrick 2004).

A list of 129 weeds that are known to infest alfalfa are in Appendix G-3 of this technical report, including the U.S. region where they are most prevalent as well as their scientific and common names.

General rules for managing weeds at establishment or in the seedling year include (Loux et al., 2007):

- Weeds that emerge with the crop are generally more destructive.
- Maintain the forage relatively weed-free for the first 60 days.
- Weeds that emerge beyond 60 days will not influence that year's forage yield.
- Later-emerging weeds may still influence forage quality.
- Winter annual weed competition in early spring is most damaging to forages.
- Broadleaved weeds are generally more competitive against legumes than grassy weeds.

4.1 Glyphosate Resistance in Weeds

Herbicide resistance can be defined as the inherited ability of a weed population to survive and reproduce following a herbicide application that is normally lethal to the vast majority of individuals of that species (lethal to the wild type) (Puricelli and Tuesca, 2005; Stoltenberg and Jeschke, no year). Farmers are concerned about glyphosate-tolerant weeds (Johnson and Gibson 2006). Figure G-3 represents the different weed populations in alfalfa. Since 1998, 14 new glyphosate resistant weeds have been found globally. Nine of these have glyphosate resistant biotypes in the United States. Eight of the new glyphosate resistant weeds known globally are also known to be weeds in alfalfa stands (see Appendix G-3 in this technical report for list of weeds in alfalfa). At least 21 weeds that have natural resistance to glyphosate exist. Ten of these naturally glyphosate resistant weeds are known to be a problem in alfalfa. Table G-7 lists

the weeds known to be glyphosate resistant in general or have glyphosate resistant biotypes. Figure G-4 summarizes the results of a recent farmer survey regarding their satisfaction with GT alfalfa and which weeds were controlled.

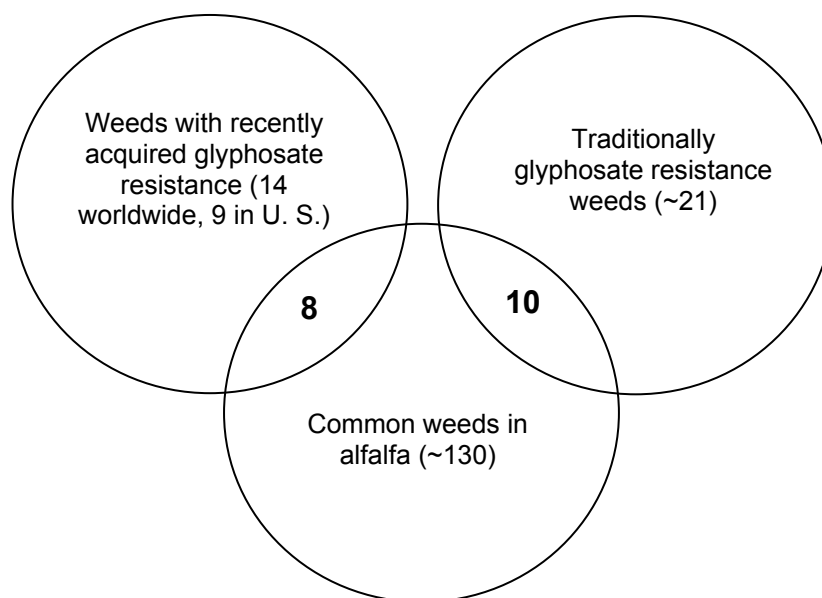

Figure G-7: Weeds in alfalfa

Table G-7. Glyphosate-resistant weeds

Common Name	Scientific Name	Resistant Biotype Reported in U.S.	Identified Problem in Alfalfa (Appendix G-3)	Listed on Roundup® Label	Source
Recently Evolved or Selected Resistant Biotypes					
Common Ragweed	<i>Ambrosia artemisiifolia</i>	Yes	Yes	Yes (with resistant biotype note)	Heap et al., 2008
Common Waterhemp	<i>Amaranthus rudis</i> and <i>Amaranthus tuberculatus</i>	Yes	No	Yes (with resistant biotype note)	Heap et al., 2008; Nandula et al., 2005
Giant Ragweed	<i>Ambrosia trifida</i>	Yes	No	Yes (with resistant biotype note)	Heap et al., 2008
Hairy Fleabane	<i>Coryza bonariensis</i>	Yes	No	Yes	Heap et al., 2008; Nandula et al., 2005
Horseweed	<i>Coryza canadensis</i>	Yes	Yes	Yes (with resistant biotype note)	Heap et al., 2008; Nandula et al., 2005

Italian Ryegrass	<i>Lolium multiflorum</i>	Yes	Yes	Yes (with resistant biotype note)	Heap et al., 2008; Nandula et al., 2005
Johnsongrass	<i>Sorghum halepense</i>	Yes	Yes	Yes (mixture also recommended)	Heap et al., 2008
Palmer Amaranth	<i>Amaranthus palmeri</i>	Yes	Yes	Yes (with resistant biotype note)	Heap et al., 2008
Rigid Ryegrass	<i>Lolium rigidum</i>	Yes	No	Yes (with resistant biotype note)	Heap et al., 2008; Nandula et al., 2005
Buckhorn Plantain*	<i>Plantago lanceolata</i>	No	Yes	No	Heap et al., 2008
Goosegrass	<i>Eleusine indica</i>	No	Yes	Yes	Heap et al., 2008; Nandula et al., 2005
Junglerice	<i>Echinochloa colona</i>	No	Yes	Yes (mixture also recommended)	Heap et al., 2008
Sourgrass	<i>Digitaria insularis</i>	No	No	No	Heap et al., 2008
Wild Poinsettia	<i>Euphorbia heterophylla</i>	No	No	No	Heap et al., 2008

Historically Naturally Resistant					
Asiatic dayflower	<i>Commelina communis</i>		No	No	Nandula et al., 2005

Cline 2004 reports that fleabane and henbit are also difficult to control with glyphosate. * These 3 weeds are not fully controlled by any of the 16 herbicides listed in the University of California Pest Management Guidelines (Rogan and Fitzpatrick 2004).

Survey of GT Alfalfa Farmers

Canevari (2007) reported survey results from interviews with alfalfa growers and industry representatives from California, Idaho, Nevada, Arizona, Washington, and New Mexico (43 respondents). The major weeds in alfalfa that were controlled by using a GT alfalfa system are listed below. Weeds that were cited as causing problems in alfalfa but were not mentioned by farmers as being controlled by glyphosate are highlighted in grey. A more comprehensive list of weeds in alfalfa is in appendix B.

Of the 24 growers surveyed all were satisfied with GT alfalfa. Advantages included less herbicide needed, yield increase, control of volunteer crops, excellent weed control, hay quality increase, better stand and water efficiency. Farmer concerns were that the seed is no longer available, the need for bale identification due to court order, and reluctance of the horse market. For the pest consultants, dealers, and researchers, concerns included export concerns, seed costs, weed resistance, weed shifts, market acceptance.

Bindweed	Dandelion	Knapweed	Morningglory
Bur clover	Dodder	Knotweed	Nutsedge
Canada thistle	Fiddleneck	Kochia	Pepperweed
Cocklebur	Foxtail	London rocket	Plantain
Common groundsel	Hoary cress	Lovegrass	Pigweed
Curly dock	Johnson grass	Mexican tea	Quackgrass
			Water grass

Figure G-4: Survey of GT alfalfa farmers

The 18 weed species (table G-7) that are both resistant to glyphosate and traditionally present problems in alfalfa likely pose the greatest threat for weed shifts in a GT cropping system. Eight weeds with newly identified resistance and ten weeds known to have some natural resistance to glyphosate are briefly described below.

4.1.1 New Glyphosate Resistant Weeds

Glyphosate resistant biotypes have recently been identified for the following eight weeds that are also common in alfalfa: common ragweed, horseweed, Italian ryegrass, Johnsongrass, Palmer Amaranth, buckhorn plantain, goosegrass, and junglerice. Each is briefly discussed below.

Common ragweed (*Ambrosia artemisiifolia*) germinates in May and early June, flowers in August to September, and sets seed in September. Each plant can release more than 30,000, three mm-long seeds, which can remain viable for more than 39 years buried. Seeds are dispersed by water and animals and can be blown across crusted snow in the winter. Common ragweed can thrive in soil containing high amounts of clay, gravel, or sand. It is found in cropland, abandoned fields, vacant lots, fence rows, waste areas, and along roadsides and railroads. Because it can accumulate large quantities of trace metals, it is very competitive and can cause nutritional deficiencies in crops. Not only does it taste bitter to livestock but it also causes nausea and mouth sores in livestock. It is very difficult to control as it can tolerate mowing, trampling, and grazing (Lanini, no year a). Common ragweed has a biotype that has multiple herbicide resistance to acetolactate synthase (ALS) inhibitors and PPO inhibitors (Heap et al., 2008).

Horseweed (*Conyza canadensis*) is a summer or winter annual that grows 1.5 to 6 feet tall (Loux et al., 2006). It produces a large number of seeds (200,000 per plant) that are wind-

dispersed. Seed dispersal in a corn field ranged from 12,500 seeds per square yard at 20 feet from the seed source, to more than 125 seeds per square yard at 400 feet from the seed source (Loux et al., 2006). Seeds can disperse a quarter mile when winds are only 10 miles per hour (Barnes et al., 2003). Seeds are able to germinate in no-till fields (undisturbed soil, includes non-crop sites) and tilled fields. Outcrossing among horseweed occurs at 1.2 to 14.5 percent which facilitates the spread of resistance traits (Stoltenberg and Jeschke, no year; Nandula et al., 2005; Loux et al., 2006). The known cases of glyphosate-resistant horseweed are characterized by frequent use of glyphosate, little or no use of alternative herbicides that control horseweed, and long-term no-tillage crop production practices (Loux et al., 2006). In addition to direct competition for light, water, and nutrients, horseweed can host the tarnished plant bug, an alfalfa pest, and the viral disease aster yellows, which is transmitted by aster leafhoppers to a wide variety of plants (Loux et al., 2006). Horseweed contains volatile oils, tannic acid and gallic acid that may cause mucosal and skin irritation in livestock (especially horses) and humans (Steckel, no year a). There are horseweed biotypes that are also resistant to ALS inhibitors. Several herbicides are effective at the rosette stage, but once horseweed is over six inches tall a three-way mixture of glyphosate, plus 2,4-D ester, plus chlorimuron or cloransulam, is recommended. Biotypes that are resistance to glyphosate and/or ALS inhibitors cannot be effectively controlled (Loux et al., 2006). In Ohio, a biotype that is resistant to both ALS inhibitors and glyphosate and a biotype in Michigan that is resistant to photosystem II inhibitors and ureas and amides have been identified (Heap et al., 2008). Over 500,000 acres in the Midwest are reported to be infested with glyphosate-resistant horseweed (Cline 2004). Others estimate that over two million acres in the U.S. are infested (Heap et al., 2008).

Italian Ryegrass (*Lolium multiflorum*) is an annual grass and is related to perennial ryegrass (*Lolium perenne*). Italian ryegrass can be intentionally cultivated with alfalfa as a companion crop and is good for grazing, hay, and silage (Hall 1992). However in cool, wet environments, it may outcompete alfalfa and, in very dry situations, it might not provide adequate ground cover (Schneider and Undersander 2008). Italian ryegrass is a weed in wheat because it stays green longer than wheat and causes cut wheat to heat and spoil (Peeper 2000). There are biotypes that exhibit multiple herbicide resistance to acetyl-CoA carboxylase (ACCase) inhibitors, ALS inhibitors, and Chloroacetamides (Heap et al., 2008). At least 5,000 acres in CA are reported to be infested with glyphosate resistant ryegrass (Cline 2004).

Johnsongrass (*Sorghum halapense*) is one of the ten most noxious weeds in the world. It is a fast-growing competitive perennial grass. Established Johnsongrass can be seven to nine feet tall and releases chemicals that inhibit surrounding plant growth. A plant produces 100 to 400 seeds that withstand silage and passage through livestock digestive systems. Seeds can germinate from 6 inches deep and are viable for three years. Stresses that interrupt normal growth, such as freezing, cutting, wilting, trampling, and herbicide exposure, can cause the release of toxic amounts of hydrocyanic acid which are poisonous to livestock. Johnsongrass is thought to be introduced from Egypt sometime after the Revolutionary War and was previously grown as forage in the south. If herbicides are not used it can be controlled by intense grazing and mowing for two years until the rhizomes are depleted. (CDFA, no year a; Lanini no year b). There are separate biotypes of Johnsongrass that have resistance to ACCase inhibitors, Dinitroanilines and ALS inhibitors (Heap et al., 2008).

Palmer amaranth (*Amaranthus palmeri*) is closely related to waterhemp and is the dominant pigweed in the Southwest. It is the most competitive and rapidly growing species of the weedy pigweeds and can reach a height of six feet (Steckel no year b). It is susceptible to herbicides when it is 4 to 6 inches tall (Scarpitti et al., 2007). Biotypes of Palmer amaranth have been identified with resistance to Dinitroanilines, photosystem II inhibitors, and ALS inhibitors (Heap et al., 2008).

Buckhorn Plantain (*Plantago lanceolata*) competes with crops for soil nutrients, water, and light and does well in droughts. It reproduces by seed and by tap root. Buckhorn plantain establishes slowly in alfalfa, but, once established, is difficult to control because of its extensive crown system (Wall and Whitesides, 2008). Glyphosate resistance is the only identified herbicide resistance in buckhorn plantain and has only been found in South Africa, so far (Heap et al., 2008).

Goosegrass (*Eleusine indica*) is an annual grass with an extensive root system that can produce 50,000 seeds per plant (Duble, no year). It is one of the five most troublesome weeds worldwide. It is found in agricultural fields, homeowner lawns, waste areas, roadsides, pastures, and golf courses. When it emerges with or shortly after a crop it can be a very competitive weed. Later in the growing season, it can produce enough biomass to hinder harvest (Steckel no year c). Some goosegrass biotypes exist that are known to be resistant to ACCase inhibitors, Bipyridiliums, Dinitroanilines, and ALS inhibitors. In Malaysia, a case of multiple resistance to ACCase inhibitors and glyphosate was found (Heap et al., 2008).

Junglerice (*Echinochloa colonum*) is a summer annual grass that is invasive in Tennessee, Hawaii, and Arizona (NPS 2007). It has little or no dormancy in tropical areas and germinates throughout the year. It can grow two to three feet high (Virginia Tech, no year). In Costa Rica, a biotype has been identified that has multiple resistance to ACCase inhibitors, ALS inhibitors, and ureas and amides. A glyphosate resistant biotype has been identified in Australia (Heap et al., 2008).

4.1.2 Traditionally Glyphosate Resistant Weeds

Ten weeds that are common in alfalfa and historically have some tolerance for glyphosate include bermudagrass, burning nettle, cheeseweed, common lambsquarters, field bindweed, filaree, large crabgrass, morningglory, nutsedge, and purslane. Each is briefly discussed below.

Bermudagrass (*Cynodon dactylon*) is a perennial grass that propagates through seed, root, or stem cuttings. If bermudagrass is cultivated, the soil should be dry because, if it is moist, the cut shoots will form new plants (Cudney and Elmore 2007). Bermudagrass is also grown as a forage crop (Undersander and Pinkerton 1988).

Burning nettle (*Urtica urens*) is a summer annual that flowers from June to November and is wind-pollinated. One plant can produce from 1,000 to 40,000 seeds. When left undisturbed in soil for six years, germination declined by 61 percent. However, 20 to 100 year-old seeds from excavations have been known to germinate. Seeds can also survive livestock digestive systems (Organic Garden 2007). Burning nettle stinging hairs contain histamine, formic acid, acetylcholine, acetic acid, butyric acid, leukotrienes, 5-hydroxytryptamine, and other irritants.

Dermal contact with the hairs leads to a mildly painful sting and itching or numbness for a period lasting from minutes to days (Thorne Research 2007). In Australia, a biotype resistant to photosystem II inhibitors has been identified (Heap et al., 2008).

Cheeseweed (*Malva neglecta*) is an annual or biennial dicot that reproduces from seeds. It is found on cultivated ground, new lawns, farmyards, and waste places (Mitich, no year). It is very competitive in alfalfa and, once established, is difficult to control. The fatty acids malvalic acid and sterculic acid may cause the plant to be toxic to horse, cattle, and sheep (Canevari 1997). Selenium or nitrate concentration has also been cited as the cause of toxicity (Hill 1993; USU, no year; Barnard, 1996).

Common lambsquarters (*Chenopodium album*) is a summer annual dicot that is adaptable to many environments. A plant can produce 100,000 seeds which can survive 30 to 40 years in soil (Lanini, no year c). Biotypes that are resistant to photosystem II inhibitors and ALS inhibitors have been identified in the United States (Heap et al., 2008). Glyphosate resistant lambsquarters has been reported in the Midwest and in a Madera, CA almond orchard (Cline 2004).

Field bindweed (*Convolvulus arvensis*) is a perennial dicot that reproduces by seed and vegetatively from deep-creeping roots and rhizomes. Young plants seldom produce seed in the first year, but one plant can produce 500 seeds. In fields, seeds can survive 20 years or more. Field bindweed can harbor the viruses that cause potato X disease, tomato spotted wilt, and vaccinium false bottom. In addition, it contains tropane alkaloids and can cause intestinal problems in grazing horses (CDFA no year b).

Filaree (*Erodium cicutarium*) is a winter annual dicot that grows two to five inches high. It is adapted to a broad range of soil types and is found in oak woodlands, semi-desert grassland, desert shrublands, fields, lawns, and wastelands. Redstem filaree can be excellent forage for livestock and wildlife, but can cause bloating under heavy grazing (Pratt et al., 2002). It is competitive with crops and can cause yield reductions (Trainor and Bussan 2001).

Large crabgrass (*Digitaria sanguinalis*) is a summer annual that reproduces by seeds (Stritzke, no year). It is primarily a turfgrass weed, but can be founding thinning alfalfa stands (Elmore 2002). A biotype with multiple resistance to ACCase inhibitors and ALS inhibitors has been identified in Australia. Photosystem II inhibitor resistant biotypes have also been identified (Heap et al., 2008).

Morning glory (*Ipomoea purpurea*) is a perennial climbing vine that reproduces by seed (Pittwater Council, no year). It is a problem in crops because of competition. Morning glory seeds are toxic to humans (Filmer, no year). Morning glory foliage is toxic to livestock due to nitrates. Symptoms of acute nitrate poisoning are trembling, staggering, rapid breathing, and death. Chronic poisoning may result in poor growth, poor milk production and abortions. In cattle, there is evidence that vitamin A storage is affected (Robinson and Alex 1989).

Nutsedge (*Cyperus* spp.) is a hardy weed due to tubers that grow 8 to 14 inches below the ground and, when mature, can re-sprout 10 to 12 times after cutting before tuber resources are depleted. In addition, many herbicides are not translocated to tuber, and, therefore, do not

effectively control growth (Wilén et al., 2003). Alfalfa should not be planted in a field where nutsedge is a known problem (Canevari et al., 2003). In a study in California, nutsedge was reduced 96 to 98 percent using crop rotation and herbicides. The rotation was two years alfalfa with applications of EPTC herbicide, two years of barley double-cropped with corn and application of thiocarbamate herbicide, and two years of barley followed by fallow glyphosate applications (Canevari et al., 2007). Biotypes of *Cyperus difformis* that are resistant to ALS inhibitors have been found in California and globally (Heap et al., 2008).

Purslane (*Portulaca oleracea*) is a summer annual dicot that produces 240,000 seeds per plant and can survive five to 40 years. It can re-root after cultivation or hoeing, so it is difficult to control mechanically. It is a minor crop in the United States because it is edible and is used in ethnic cooking. In other crops, it is a weed because of competition (Cudney et al., 2007).

4.1.3 Mechanisms of Glyphosate-Tolerance

Glyphosate inhibits 5-enolpyruvylshikimate-3-phosphate (EPSP) synthase, which is a key enzyme in the shikimate pathway in plants and is required for plant growth. The effects of glyphosate can be stopped in several ways (Cerdeira and Duke, 2006; Stoltenberg and Jeschke, no year; Nandula et al., 2005):

Resistant EPSP synthase - A version of EPSP synthase that is not affected by glyphosate has been found in bacteria (*Agrobacterium*) and has been transferred into crop plant genomes. Also, the maize version of EPSP synthase has been modified by site directed mutagenesis to be resistant to glyphosate. A version of EPSP synthase with decreased binding to glyphosate has been found in the weed goosegrass (*Eleusine indica*).

Degrade glyphosate - A glyphosate-degrading enzyme has been found in bacteria (*Ochrobactrum ananthropi*) and has been transferred into crop plant genomes.

Inactivate glyphosate - An enzyme found in bacteria (*Bacillus licheniformis*) has a weak ability to inactivate glyphosate through N-acetylation. The efficiency of this enzyme was increased by directed evolution in the lab and, when transferred to plants, confers resistance to glyphosate in field settings. A fungal gene encoding glyphosate decarboxylase has been discovered and patented for eventual use in crop plants.

Altered translocation of glyphosate – There is limited evidence that, in some glyphosate resistant ryegrass, glyphosate accumulates in mature leaf tissue rather than in the growing parts. Although the mechanism of resistance in horseweed is unknown, translocation experiments suggest that resistant biotypes do not translocate glyphosate to the growing parts of the plant (e.g., roots, young leaves, and crown).

Other – Resistant plants exist for which the mechanism of glyphosate resistance is not known. In addition, it is likely that there are mechanisms of resistance that have yet to evolve.

4.2 Weed Shifts in GT Alfalfa

Adopting new weed control strategies eventually leads to shifts in the weeds that are of greatest concern. Weed shifts can occur due to changes in tillage, irrigation, soil fertility, planting date, crop rotation, and herbicide use (Hilgenfeld et al., 2004). Changes to a no-till system results in a more diverse seedbank. Within weedy species variations in characteristics help weeds escape or tolerate weed management. These characteristics include seed dormancy, emergence patterns, growth plasticity, life cycle, life duration, shade tolerance, late-season competitive ability, seed dispersal mechanisms, and morphological and physiological variations (Hilgenfeld et al., 2004).

Because weed seedbanks in the soil can contain large reservoirs of dormant weed seed, short-term studies (a few years) might not detect the full potential shift in weed communities (Harker et al., 2005). However sometimes weeds shift can be observed within a few years. For example, in a field trial in an established GT alfalfa stand in the Southwest (San Joaquin Valley) burning nettle was not controlled and the population of burning nettle increased significantly over the three-year trial period (Canevari et al., 2004; Van Deynze et al., 2004). Tank mixtures with Velpar (hexazinone) or paraquat controlled burning nettle. Weeds that are difficult to control with glyphosate, such as dodder and cheeseweed, may need to be treated early and require a second application. Van Deynze et al (2004) recommend that the best way to prevent weed shifts is to avoid using the same herbicide year after year, rotate herbicides and crops, and include non-herbicide strategies to control weeds.

Puricelli and Tuesca (2005) found that continuous (once before planting, once at 40 days after planting, once in winter fallow in August) glyphosate application in field studies on three crop rotation sequences and two tillage systems lead to quantitative and qualitative changes in weed communities. They found that glyphosate application was a more important factor than crop sequence to explain weed community changes in summer crops. They also predicted that continual glyphosate application for longer than the five years in their study might lead to the development or higher increases in abundance of weeds tolerant to glyphosate. Weed species diversity in conventional versus no-tillage plots did not differ significantly.

Harker et al., (2005) reported that field studies of spring wheat-canola-spring wheat rotations of various combinations of GT and non-GT varieties under conventional tillage or low soil disturbance direct seeding systems indicate that weed community shifts are dependent on rotation pattern in a site-dependent manner. In the western Canada field locations, within 3 years, crop systems without GT varieties were associated (using canonical discriminant analysis) with green foxtail, redroot pigweed, sowthistle spp., wild buckwheat, and wild oat. The specific weeds associated with all GT variety systems included Canada thistle at the Brandon site, henbit at the Lacombe site, and volunteer wheat, volunteer canola, and round-leaved mallow at the Lethbridge site. One surprising finding was that high variability in wild buckwheat between the systems. Glyphosate is not very effective on wild buckwheat, so the authors propose that wild buckwheat seed production or viability may be restricted by glyphosate more than the wild buckwheat biomass. Therefore after glyphosate application the plant may appear visually robust, but its ability to reproduce has been effected, so in following years less wild buckwheat is observed (Harker et al., 2005).

It is plausible that the 18 weeds discussed in section 4.1 are the first candidates for weed shifts in GT alfalfa. However, as discussed in the studies summarized above, weed shifts are dependent on the composition of the weed seedbank in the soil and surrounding sources of weeds.

4.2.1 Weed Management Options

Weed management strategies in organic alfalfa systems, conventional alfalfa systems, and glyphosate-tolerant alfalfa systems differ. Management options for conventional systems include (Nandula et al., 2005; Guerena and Sullivan 2003):

- Chemical (See table G-6)
 - Alternating herbicides with different modes of action
 - Tank mixing herbicides
 - Sequences of herbicides
 - Application timing
- Cultural
 - Rotation between GT cultivars and non-GT cultivars
 - Winter crops in rotation
 - Companion crops/co-cultivation/interseeding/nurse crop)
 - Cover crops (smother crops) (prior to planting alfalfa)
 - Field scouting for early detection
 - Monitor for weed species and population shifts
- Mechanical
- Tillage cultivation

Organic alfalfa systems can use the cultural and mechanical strategies (except for use of GT cultivars). Nurse crops of peas or oats produce good hay for the horse market (Guerena and Sullivan 2003). GT alfalfa systems can use all of the strategies of conventional systems plus application of glyphosate directly on growing alfalfa. Options for rotating between GT cultivars and non-GT cultivars are reduced with GT alfalfa, since GT corn and GT soybean are popular rotation crops for alfalfa.

Cutting intervals affect weed infestation. For example, if alfalfa is cut too frequently (20 to 25 days) there is not enough time for root storage of carbohydrates so growth after cutting is not vigorous and weeds have a competitive advantage. However sometimes early harvest can rescue a heavily weed-infested new stand if the weeds are beyond the stage of optimum herbicide treatment (Canevari et al, 2007). Alternating long and short intervals between cuttings enables alfalfa to maintain root reserves so plants can recover from defoliation quickly and more vigorously compete with weeds (Canevari et al, 2007).

4.3 Distribution of Glyphosate Resistant Weeds

Table G-8 shows that currently 19 U.S. states are affected by glyphosate resistant weeds. The majority of new glyphosate resistant weeds are located in the Southeast and Midwest. The overlap with the major alfalfa producing states in the Intermountain regions seems to be minimal at this point (table G-6). However, given that there is overlap between glyphosate resistant weed locations and alfalfa hay acreage there is potential for rapid shifts of glyphosate resistant weeds

into GT alfalfa fields if GT alfalfa were to be widely adopted. California is a concern because glyphosate resistant weeds are present and alfalfa is a major crop in California. More detailed records of local weed infestations may be kept by state extension offices.

Table G-8. Glyphosate-Resistant Weed Infestations by State (Heap et al., 2008)

State	Weed species	~ Number of Sites in State Infested	~ Number of Acres in State Infested	Situation	Year Reported
Arkansas	<i>Conyza canadensis</i> Horseweed	6-10 increasing	1,001-10,000 increasing	Cotton	2003

* resistant to chlorimuron-ethyl, cloransulam-methyl, and glyphosate ** resistant to acifluorfen-Na, cloransulam-methyl, fomesafen, glyphosate, imazamox, imazethapyr, and lactofen *** resistant to chlorimuron-ethyl, glyphosate, and imazethapyr

Monsanto's guidance for weed resistance management in GT alfalfa is as follows (Monsanto 2008):

- Scout fields before and after each herbicide application.
- Use the right herbicide product at the right rate and at the right time.
- To control flushes of weeds in established alfalfa, make applications of Roundup WeatherMAX herbicide at 22 to 44 oz/A before weeds exceed 6", up to 5 days before cutting.
- Use other herbicide products tank-mixed or in sequence with Roundup agricultural herbicide if appropriate for the weed control program.
- Report repeated non-performance to Monsanto or your local retailer.

4.4 Summary of Findings

At least 129 different weed species are identified as minor or major problems in alfalfa. Out of 14 new glyphosate resistant weeds found since 1998, eight are known to be weeds in alfalfa. Out of at least 21 weeds that have natural resistance to glyphosate, ten are known to be a problem in alfalfa. These 18 weeds that are both resistant to glyphosate and traditionally listed as problems in alfalfa include: common ragweed, horseweed, Italian ryegrass, Johnsongrass, Palmer Amaranth, buckhorn plantain, goosegrass, junglerice, bermudagrass, burning nettle, cheeseweed, common lambsquarters, field bindweed, filaree, large crabgrass, morningglory, nutsedge, and purslane. Although the composition of weed shifts is based on the local seedbank, these 18 weeds are candidates for becoming more prevalent than GT sensitive weeds in rotations that include GT alfalfa.

Mechanisms of glyphosate resistance include resistant EPSP synthase, degradation of glyphosate, inactivation of glyphosate, and altered translocation of glyphosate.

Nineteen states and over two million acres of cropland are infested with new glyphosate resistant weeds. The heaviest infestation is in the Southeast and Midwest. Overlap with the major alfalfa producing states in the Intermountain regions seems to be minimal at this point. However, given that there is overlap between glyphosate resistant weed locations and alfalfa hay acreage there is potential for rapid shifts of glyphosate resistant weeds into GT alfalfa fields if GT alfalfa were to be widely adopted. California is a concern because glyphosate resistant weeds are present and alfalfa is a major crop in California.

Weeds are controlled in conventional alfalfa with chemicals (herbicides), cultural methods (rotation, companion crops, monitoring), and mechanical methods (tillage). The cultural and mechanical methods are permitted for organic farmers. GT systems allow for the use of one additional herbicide, glyphosate.

Appendix G-2. Literature Search

1.0 Literature Search Strategy

The following literature search was done for two of the technical reports:

Effects of Glyphosate-tolerant weeds in agricultural systems (former title: Increase in RR resistant weeds in crops)

Effects of Glyphosate-tolerant weeds in non-agricultural ecosystems (former title: Increase in RR resistant weeds in non-crop ecosystems)

1.1 Purpose

The purpose of this literature search is to locate references about the potential impacts of glyphosate-tolerant weeds in agricultural systems and in natural ecosystems.

The following DIALOG databases were included in the search:

- ☐ File 10:AGRICOLA 70-2008/Jun
- ☐ (c) format only 2008 Dialog
- ☐ File 156:ToxFile 1965-2008/Jun W2

Descriptions of these files are available at <http://library.dialog.com/bluesheets/>.

1.2 Scope of Search

The search focused on any published references between 2000 and the present. A list of titles was screened followed by screening of abstracts for relevant titles. There were no limits on language for titles but only English language publications were retrieved for evaluation.

1.3 Keywords

A list of search parameters is listed below.

Synonyms of key topic
Glyphosate toleran*
Glyphosate resistan*
Roundup® Ready

Key words in combination with key topic Weed management Weed mitigation Weed control
Alfalfa
Medicago
Evolution

1.4 Results

Alfalfa management in no-tillage corn
2006
Glyphosate-*resistant* corn was no-till planted into *alfalfa* that was in the early bud stage (UNCUT) or had been cut 3 to 4 d earlier and baled for hay (CUT). *Alfalfa* control and corn yield were measured in nontreated plots as well as plots treated with.....or tank-mixed with 2,4-D or dicamba applied at planting (AP) or POST. *Alfalfa* control was greater for all AP treatments of UNCUT compared to CUT *alfalfa*. Glyphosate plus dicamba applied AP controlled *alfalfa* better than the other AP treatments resulting in increased corn yield compared with other

AP...Postemergence applications of glyphosate alone or tank-mixed with 2,4-D or dicamba controlled *alfalfa* better 6 weeks after treatment than AP applications of the same herbicides; however, corn yield..... same herbicides. Corn yield averaged 13% higher following herbicide applications to UNCUT compared with CUT *alfalfa*, so the value of *alfalfa* hay must be weighed against the loss of corn yield when making decisions concerning the management of an *alfalfa*-corn rotation. Descriptors: Zero tillage; *Weed* control; *Weed* science; *Medicago* sativa

Comparing *Roundup* *Ready* and Conventional Systems of *Alfalfa* Establishment

2007

URL: <http://dx.doi.org/10.1094/FG-2007-0724-01-RS>

Roundup *Ready* (RR) technology provides a new approach for *weed*

□ control during *alfalfa* (*Medicago* sativa L.) establishment. We determined the effect of RR and conventional establishment systems on *alfalfa* yield, *weed* yield, and forage quality when *alfalfa* was established using solo-seeding or oat mulch methods. A RR system was a RR *alfalfa* in combination with glyphosate (Roundup) and a conventional system was a non-RR variety with imazamox (Raptor). Non-RR and RR alfalfas were also seeded with an oat companion crop. *Alfalfa* yields, plant populations, and forage quality were similar for the RR and conventional systems within solo-seeding and oat establishment methods in the seeding year. Total seeding-year *alfalfa* yield was greater when solo-seeded using an herbicide than when seeded with an oat companion crop harvested at boot. *Alfalfa* yield for the oat mulch and oat companion crop treatments were not consistently different over...

Role and value of including lucerne (**Medicago** sativa L.) phases in croprotations for the management of
herbicide-*resistant* *Lolium rigidum* inWestern Australia

2008 URL: <http://dx.doi.org/10.1016/j.cropro.2007.07.018>Use of lucerne (**Medicago** sativa L.) pastures in
crop rotations has been
proposed as a method to enhance *weed* management options for growersfacing *herbicide* *resistance* in
Western Australia. An existing model foranalysing *herbicide* *resistance* in the important crop *weed*
annualryegrass (*Lolium rigidum* Gaud.) is consequently extended to include lucerne, used for grazing by...options
are analysed, including variouscombinations of lucerne, annual pastures, and crops. Lucerne providesadditional
weed management benefits across the rotation, but in the region studied these benefits are only sufficient...

Winter annual *weed* control with herbicides in *alfalfa*-orchardgrass mixtures
2008

4.0 ABSTRACT: *Alfalfa*-orchardgrass hay is popular in the Western United States because of an expanding horse-hay market. However, *weed* control in mixed *alfalfa*-orchardgrass stands is problematic, as herbicides must be safe for both species. Most growers rely solely on the competitiveness of the crop for *weed* control, which is often insufficient, especially in older stands. Field experiments were established in northern California to determine the efficacy and crop safety of several herbicides for winter annual *weed* control in established *alfalfa*-orchardgrass. Metribuzin at 560 or 840 g/ha and hexazinone at 420 g/ha applied...
... Paraquat at 560 g/ha applied shortly after crop green-up gave 50 to 82% *weed* control and caused significant injury to orchardgrass, which was still noticeable at first cutting.... ORGANISMS: *Medicago* sativa { *alfalfa* } (Leguminosae) MISCELLANEOUS TERMS: *herbicide* *tolerance*

Appendix H. Effects of Glyphosate-Resistant Weeds in Non-Agricultural Ecosystems

Effects of Glyphosate-Resistant Weeds in Non-Agricultural Ecosystems

Executive Summary

The subject of this report is whether glyphosate-tolerant (GT) alfalfa or glyphosate resistant weeds that might increase in prevalence due to use of GT alfalfa are likely to present weedy problems in non-agricultural ecosystems.

Medicago sativa (alfalfa) is native to the Middle East and Central Asia and was introduced to North America over 200 years ago. *Medicago sativa* spp. *sativa* (purple-flowered alfalfa) has naturalized populations in the U.S. and occurs in all 50 states. In a survey of 940 roadside sites in 47 counties in six northwestern states, Washington had the lowest percentage of sites with feral alfalfa occurring in 10 percent of the pre-selected sites and South Dakota had the highest with feral alfalfa occurring in 63 percent of the pre-selected sites. In sites where alfalfa was present, the ground cover of alfalfa was 1.2 to 5.4 percent. At approximately 22 percent of the sites, feral populations were located 2000 meters from cultivated alfalfa.

Medicago sativa spp. *falcata*, (yellow-flowered or Siberian alfalfa) is naturalized in the more northern and western states. It is being promoted as a rangeland enhancer for grazing. A naturalized population of *falcata* that was seeded on rangeland in South Dakota in 1915 is still in existence. Hybridization between *falcata* and cultivated alfalfa would result in hybrids that would be less adapted to northern plains rangeland than the *falcata* parent, but possibly better adapted than the cultivated alfalfa parent.

Alfalfa is used for a variety of non-agricultural purposes. These uses include: rehabilitation of overgrazed rangelands, erosion-control projects in interior forests, treatment of compacted soils, re-vegetation of areas damaged by wildfire, and erosion reduction in mined soils.

Twenty four weed species are known that either have newly evolved glyphosate resistant biotypes or have historically natural resistance to glyphosate. All 24 of these have naturalized or native populations in the U.S. (although one, Chinese foldwig, is found only in Hawaii). Thirteen of the 24 glyphosate resistant weed species are on at least one noxious weed list. Nine of the 14 newly evolved glyphosate resistant weeds have documented glyphosate resistant biotypes in the U.S. The remaining 5 have sensitive biotypes in the U.S, but glyphosate resistant biotypes have not yet been documented in the U.S. An increase in the prevalence of these glyphosate resistant weeds would likely be combated with alternative herbicides, mechanical removal, and spot burning.

There is very little evidence to suggest that alfalfa is considered a weed, other than as a volunteer in agricultural settings. Out of 12 weed lists from the USDA PLANTS Database, *Medicago sativa* is only listed on one, the Southern Weed Science Society, and this listing may be due to volunteer alfalfa in cropland. Thirteen surveyed weed control experts only identified one setting, irrigation ditches in California, where GT alfalfa could not be controlled by alternative

herbicides. In this case only glyphosate is approved for irrigation ditches, so mechanical removal or spot burning would be the alternative control measures.

The USDA Forest Service uses glyphosate to manage forests. Their usage is 0.275 percent of the quantity used on agricultural lands. The Roundup® herbicide label has 41 other non-crop setting listed. Many of these setting overlap with areas where feral alfalfa is found. There is a possibility that feral GT alfalfa could be found in non-crop areas. In cases where control is desired alternative control methods are available.

1.0 Introduction

This technical report discusses the distribution and possible effects of glyphosate resistant weeds and escaped glyphosate-tolerant (GT) alfalfa in non-agricultural ecosystems. Alfalfa that is intentionally grown in agricultural fields and volunteer alfalfa in agricultural fields is not discussed in this report.

1.1 Non-Agricultural Alfalfa in the United States

Medicago sativa (alfalfa) was introduced to the United States at least 200 years ago (Putnam et al., 2001). It is native to the Middle East and Central Asia, and has adapted to many growing conditions as it has been cultivated and distributed by humans (Xu et al., 2004). Since its introduction to the U.S., alfalfa has escaped agricultural fields and become naturalized, or feral. Different settings where feral alfalfa may be found include air fields, canals, cemeteries, ditch banks, fence rows, highways, irrigation ditches, pipelines, railroads, rangeland, rights-of-way, roadsides, wasteland (Rogan and Fitzpatrick 2004). Alfalfa in non-agricultural ecosystems may be either intentionally seeded or escaped from agricultural settings. Regardless, alfalfa plants outside of cropping systems generally do not have regular external inputs like irrigation, herbicides, insecticides, and fertilizers. Sometimes the definition of feral alfalfa includes volunteer alfalfa in crop land (Bagavathiannan and Van Acker 2008). For this report, volunteer alfalfa growing out of rotation in an agricultural field with another crop (e.g., corn) is not discussed, but escaped volunteers are included. Escaped volunteers are alfalfa plants from seed that escaped from an agricultural field, creating the first generation of a possible feral population. Escaped volunteers may not persist past a generation or two, depending on environmental conditions.

There is considerable literature on wild alfalfa in regions where it is native and wild relatives exist (Appendix 1 to this technical report). In other countries, such as Spain, gene flow between wild and cultivated alfalfa has been more extensively studied than in the U.S. (Jenczewski et al., 1999). This report does not review the global body of literature on wild alfalfa; it focuses on only naturalized populations in the U.S.

One concern in the U.S. is that naturalized alfalfa could act as a reservoir for the GT trait and be a source for the trait to be present in non GT alfalfa fields (Bagavathiannan et al., 2006). Gene flow to and from naturalized alfalfa is discussed in Appendix 2 of the technical report *Economic and Social Impacts to Organic Farmers of Deregulation of Roundup Ready Alfalfa* (Appendix T). The subject for this report is whether GT-alfalfa or glyphosate resistant weeds that might increase in prevalence due to use of GT alfalfa are likely to present weedy problems in non-agricultural ecosystems.

1.2 Feral Attributes

Survival without management inputs requires that feral plants have traits that may be different from cultivated plants. Bagavathiannan and Van Acker (2008) list the following traits that are common among most successful feral species:

- Variety of pollinators
- Continuous seed production
- Considerable seed output
- Seeds produced in several habitats
- Seed dispersal over short and long distances
- Seed dormancy (ability to form a seedbank)
- Broad germination requirements
- Discontinuous germination
- Rapid vegetative growth
- Can withstand competition
- Tolerance to unfavorable biotic and abiotic conditions
- Rapid flowering

Alfalfa has many of the above attributes and competes well with other native and introduced plants in a variety of settings. Some of the intentional uses of alfalfa on non-agricultural lands are discussed in this technical report, such as habitat rehabilitation, erosion control, and rangeland rehabilitation or enhancement.

1.3 Methodology

A literature search was designed to identify peer reviewed articles and grey literature (e.g., government reports, State Agricultural Extension Office publications) on feral alfalfa (Appendix 1 of this technical report). Several DIALOG databases were searched. Google, Yahoo, and Scirus search engines supplemented the DIALOG search. Calculations for percentages of harvest were done with Microsoft Excel. Alfalfa harvest statistics were obtained from USDA's National Agricultural Statistics Service.²⁶ USDA's Agricultural Marketing Service also provided information on harvests.²⁷ The common and scientific names for weeds were found in the USDA PLANTS database (Appendix 3 of this technical report).²⁸

2.0 Alfalfa Populations

2.1 Distribution of Naturalized Alfalfa in the United States

USDA, Natural Resources Conservation Service (NRCS), National Plant Data Center, PLANTS Database provides habitat ranges and other standardized information for over 43,000 U.S. plant species.²⁹ Appendix 2 of this technical report includes U.S. distribution maps for *Medicago sativa* (purple alfalfa) and *Medicago sativa* spp. *falcate* (yellow alfalfa). For some states, county specific data are available. The PLANTS Database indicates that "county data are based primarily on the literature, herbarium specimens, and confirmed observations. Not all populations have been documented, however, and significant gaps in the distribution shown may not be real... Remember that only native and naturalized populations are mapped!" Agricultural

²⁶ <http://www.nass.usda.gov/index.asp>

²⁷ <http://www.ams.usda.gov>

²⁸ <http://plants.usda.gov/java/invasiveOne>.

²⁹ http://npdc.usda.gov/pdf/0105_npdc_brochure.pdf

distribution is not included in the PLANTS Database and the size of the naturalized population in a given area is not indicated.

Scientists at Forage Genetics and Monsanto Company conducted a six state survey of alfalfa populations in 2001 and 2002 (Kendrick et al., 2005; Rogan and Fitzpatrick 2004). Data were collected at 1040 survey sites (20 sites per county, 500m² per site). Three survey strategies were adopted. “Pre-selected” survey sites without knowledge of terrain or vegetation were selected to avoid sampling bias. “Satellite” sites were selected at or near 3 miles from each pre-selected site and were intentionally scouted for feral alfalfa. The third strategy recorded the frequency of feral alfalfa populations observed along an entire travel route. Rogan and Fitzpatrick (2004) summarized the results. Their narrative summary was converted to table H-1. In a meeting abstract Kendrick et al (2005) summarize that 940 roadside sites were surveyed in 47 counties in six states. At approximately 22 percent of the sites, feral populations were located 2000 meters from cultivated alfalfa. On average, feral populations occupied less than 3 percent of the area surveyed.

Table H-1 Summary of Six State Feral Survey (adapted from Rogan and Fitzpatrick 2004)

State (# of counties surveyed)	Feral alfalfa occurred within or near X% of pre-selected sites	Feral alfalfa occurred within or near X% of satellite sites	Cultivated alfalfa occurred near X% of pre-selected sites	Cultivated alfalfa occurred near X % of satellite sites	Average mean coverage in sites where feral alfalfa occurred	Travel route – distance between feral populations
Idaho (11)	17%	41%	44%	43%	1.7%	>12 miles
Pennsylvania (10)	ND	57%	Feral and cultivated occurred together in 10% of sites	Feral and cultivated occurred together in 21% of sites	1.2%	6-12 miles (Centre and Franklin Counties 1-3 miles)
Wisconsin (10)	ND	47% (70-80% in Dane, Grant, Shawno and Vernon counties)	Feral and cultivated occurred together in 9% of sites	Feral and cultivated occurred together in 31% of sites	1.7%	ND
California (10)	27%	67%	38%	52%	4.2%	3-6 miles
South Dakota (6)	63%	82%	ND	Feral and cultivated occurred together in 40% of sites	5.4%	3-6 miles (Hand, Harding, Tripp counties 1-3 miles)
Washington (10)	10%	ND	Feral and cultivated occurred together in 2% of sites	ND	ND	>12 miles

ND = no data provided by Rogan and Fitzpatrick 2004 summary

The distance between feral and cultivated populations also varied. In Idaho, feral and cultivated populations occurred within 2000 meters of each other in approximately three sites per county. In approximately half of those sites, the average distance was less than 20 meters. In Wisconsin, three-fourths of the sites where feral and cultivated populations occurred together had an average distance of less than 20 meters. In California, feral and cultivated populations occurred within 2000 meters of each other in approximately six sites per county. In approximately half of those sites, the average distance was less than 20 meters. The relevance of feral populations' distance from cultivated alfalfa fields is discussed in Appendix 2 of the technical report *Economic and Social Impacts to Organic Farmers of Deregulation of Roundup Ready Alfalfa* (Appendix T).

2.2 Seeding into Non-Agricultural Lands

2.2.1 Rangeland

Medicago sativa spp. *sativa* (purple-flowered alfalfa used in cultivation) only rarely becomes naturalized in North American rangelands (Xu et al., 2004). However, *Medicago sativa* spp. *falcata*, (yellow-flowered or Siberian alfalfa) is naturalized in the more northern and western states (Appendix 2 of this technical report). *Falcata* was introduced to North Dakota in the late 1800s by Dr. N.E. Hansen, who was a professor at what is now South Dakota State University at Brookings. He traveled to Europe and Asia to collect plants for the Northern Great Plains (Smith 1997). Interest in *falcata* as a rangeland plant to benefit livestock grazing has increased in the past decade partially because of a notable ranch. *Falcata* was seeded in rangeland (near Lodgepole, SD) in 1915 with a small packet of seeds from Dr. Hansen. In the 1950's, Norman "Bud" Smith, began nurturing seed to harvest and periodically reseeded the rangeland. Those *falcata* populations reproduce and survive without help (Smith 1997; Bliss 2003). In fact about 150 acres trace back to the original 1915 seeding (Smith 1997). USDA Agricultural Research Service (ARS) scientists have determined that on the Smith farm, soil organic carbon was increased by 4 percent in the 1998 seeding, 8 percent in the 1987 seeding and 17 percent in the 1965 seeding. Soil inorganic nitrogen increased from 8 to 51 percent on the interseeded pastures, which corresponded to an increased plant nitrogen content of 8 to 33 percent in the native species (Schuman and Mortenson 2003; Hess et al., 2004). Researchers are recruiting more ranchers to seed *falcata* on native rangelands (Waggener 2007; High Plains Midwest Ag Journal 2008) and are conducting rangeland seeding projects with different varieties of alfalfa (Manske 2004). Projects are ongoing in South Dakota, North Dakota, and Utah (Boe et al., 2006).

Xu et al (2004) studied the effects of naturalized *falcata* in northwestern South Dakota on native species in the Grand River National Grassland (GRNG). The GRNG is adjacent to the Smith ranch discussed above, and *falcata* has become naturalized on over 600 acres in the GRNG. As the percentage cover of *falcata* increases, the number of other plant species decreases, so plant biodiversity is less as *falcata* increases. The authors conclude that although naturalized *falcata* increases the total biomass production on semiarid rangeland, it is at the expense of species richness and native species production. At the GRNG, the highest alfalfa seed density was more than 39,000 seeds per square meter (790 kg/ha) and 99 percent of the alfalfa seeds collected from the soil seed bank were hard and viable (Xu et al., 2007).

Researchers and rangeland managers have been trying since the 1930s to find or adapt a variety of alfalfa to enhance rangeland (Berdahl et al., 1986; Berdahl et al., 1989; Lorenz 1982; Rumbaugh 1982; Sneva et al., 1964). It is unclear how widely falcata might be adopted as interseed for rangeland because USDA ARS has only begun recruiting test ranches in the last few years. Researchers have also put forth the idea that the practice of interseeding adaptable cultivars of alfalfa into native rangelands may help in the mitigation of elevated atmospheric carbon dioxide and enhance the long-term sustainability of the ecosystem (Mortenson et al., 2004).

Future widespread adoption of falcata for rangeland could influence the overall feral alfalfa populations.

The traits that are likely to contribute to falcata's survival on rangeland include (Berdahl et al., 1989):

- Root proliferation – new shoots from horizontal roots (creeping root trait)
- Broad crown development – protection from trampling and winter injury
- Dormancy during midsummer in drought – low forage production in dry years with regrowth and blossom after late rain
- Slow regrowth compared to cultivated alfalfa (slow decumbent regrowth – lying or growing on the ground but with erect or rising tips) – possibly a grazing survival mechanism
- Hard seed that remains viable over extended periods of drought

These traits may enhance alfalfa in semiarid rangeland, but may have no utility in more humid environments where maximum forage yields from multiple harvests are desired (Berdahl et al., 1989). Expression of traits that are important for feral survival in semiarid rangeland can be masked in performance tests, because performance tests are seeded in narrow rows with high plant densities, in monoculture, are often irrigated, and are usually maintained for short periods (2 to 5 years) (Berdahl, et al., 1989).

A few examples of alfalfa cultivars that have falcata germplasm in their parentage include: Drylander, Roamer, Swift Current S3703L, Travois, South Dakota T25SYN2, Spredor 2, Alaska Synthetic A, Mandan MAL34, Alaska Synthetic B, Alaska Falcata Strain, Colorado C-3, and Mandan MAL 33 (Berdahl et al., 1989). Gimm and Ranger are also known to have falcata in their parentage (Rumbaugh, 1982). Alfalfa cultivars and experimental strains with a high proportion of falcata parentage are better adapted to interseeding into rangeland in the Northern Great Plains than traditional hay-type cultivars which have a high proportion of sativa parentage (Berdahl et al., 1989).

It is reasonable to predict that hybridization between rangeland falcata and GT alfalfa varieties with mostly sativa parentage, would result in hybrids with more rangeland hardiness than the original GT alfalfa but less rangeland hardiness than the falcata parent. It is possible that a falcata hybrid with the GT trait could establish in rangeland habitats and serve as a reservoir for the GT trait.

2.2.2 Rehabilitation and Erosion Control

Sullivan (1992) reviewed alfalfa use for rehabilitation and disturbed sites. Some of the uses that lead to feral alfalfa populations include:

- Rehabilitation of overgrazed rangelands for improvement of both wildlife habitat and livestock
- Erosion-control projects in interior forests
- Beneficial for compacted soils (alfalfa has deep roots that will grow vigorously in compacted soils)
- Re-vegetation of areas damaged by wildfire (Oregon DFW 2008)
- Erosion reduction in mined soils (also increased forage value, and as a soil conditioner in mined soils)(Sullivan (1992) cites examples in Montana, Illinois, Arizona; also Yukon mine sites (Withers 2002))

Alfalfa was found to survive and increase on rangeland in Utah for more than 10 years and can reseed on sites with as little as 11 inches (28 cm) of precipitation a year (Sullivan 1992).

When the Bureau of Land Management (BLM) toured sites in eastern Oregon that had undergone seeding treatment 35 to 40 years prior to the tour, they noted that Nomad alfalfa cultivar, which had been seeded in 1966 (36 years before 2002), was still scattered sparingly at each site (Kindschy et al., 2002).

As an example of what one state recommends for rehabilitation after wildfires, the Oregon Department of Fish and Wildlife recommends alfalfa as one component of seeding mixtures, which can sometimes contain over 20 different plant species. Recommended alfalfa quantities (only) are as follows (Oregon DFW 2008):

- Southwest Oregon Elk Mix – 7% alfalfa
- North Central Oregon Precipitation Zones, 12-20 inches and 18-30 inches - Ranger and Ladak alfalfa, 1 lb/acre each
- Central Oregon, greater than 12 inches precipitation - Ranger or Ladak alfalfa, 2 lbs/acre each (if appropriate)
- Central Oregon, less than 12 inches precipitation - Ranger or Ladak alfalfa, 1-2 lbs/acre each (if appropriate)
- Northeast Oregon, dry south-facing slopes with little soil - Ladak alfalfa, 1 lb/acre
- Northeast Oregon, north slopes or flat areas with soil and some broken shade quality (charred sticks count) - Ladak alfalfa, 2 lb/acre
- Northeast Oregon, north slopes/flat areas with soil, some broken shade quality only with rocks or little soil - Ladak alfalfa, 1 lb/acre
- Wallowa County - If grazed, Rhizoma or Spreader, 2 lbs/acre, if not grazed, Ladak, 2 lbs/acre
- Baker County Range Mix - Nomad Alfalfa, 1-2 lbs. in mix
- South Central and Southeast Oregon seed mixes, for sagebrush steppe and upland environments with 9-12 inches precipitation (Common Mix), seed mixes for saline or alkali soils and areas of poor drainage, seed mixes for rangelands with 9-12 inches precipitation (Common Mix), Seed mixes for rangelands with less than 9" precipitation. – alfalfa listed, but unspecified quantity

- South Central and Southeast Oregon Sandy or Loam Soils – alfalfa, 2 lbs/acre

To put the above seeding rates in context, irrigated agricultural alfalfa is seeded at 12 to 15 pounds per acre under ideal conditions, 15 to 20 pounds per acre when drilling, and 20 to 25 pounds per acre when broadcasting. Typically only 60 percent of the seeds germinate and 60 percent of the emerged seedlings may die during the first year. Four pounds per acre equals 20 seeds per square foot (Orloff et al., 1997). Therefore, two pounds per acre equals 10 seeds per square foot, six of which may germinate. Seedling survival would depend on the competing species. Alfalfa is included in almost all of the wildfire rehabilitation mixes. Even though the seeding rate is low, populations from rehabilitated lands could contribute to the feral population of alfalfa. As mentioned previously, to what degree feral alfalfa would serve as a reservoir for transgenes is discussed in Appendix 2 of the technical report *Economic and Social Impacts to Organic Farmers of Deregulation of Roundup Ready Alfalfa* (Appendix T).

2.3 Summary of Findings

Medicago sativa spp. *sativa* has naturalized populations in the U.S. and occurs in all 50 states. In a survey of 940 roadside sites in 47 counties in six states, Washington had the lowest percentage of sites with feral alfalfa occurring in 10 percent of the pre-selected sites and South Dakota had the highest, with feral alfalfa occurring in 63 percent of the pre-selected sites. In sites where alfalfa was present, the ground cover of alfalfa was 1.2 to 5.4 percent. At approximately 22 percent of the sites, feral populations were located 2000 meters from cultivated alfalfa.

Medicago sativa spp. *falcata*, (yellow-flowered or Siberian alfalfa) is naturalized in the more northern and western states. It is being promoted as a rangeland enhancer for grazing. A naturalized population of *falcata* that was seeded on rangeland in South Dakota in 1915 is still in existence. Hybridization between *falcata* and cultivated alfalfa would result in hybrids that would be less adapted to northern plains rangeland than the *falcata* parent, but possibly better adapted than the cultivated alfalfa parent.

Alfalfa is used for a variety of non-agricultural purposes. These uses include; rehabilitation of overgrazed rangelands, erosion-control projects in interior forests, treatment of compacted soils, re-vegetation of areas damaged by wildfire, and erosion reduction in mined soils.

3.0 Glyphosate-Resistant Weeds

3.1 Potential Glyphosate-Resistant Weeds in Non-Agricultural Ecosystems

The use of GT-alfalfa could conceivably increase the occurrence of glyphosate resistant weeds, which may impact non-agricultural lands. However, as discussed in the technical report *Effects of Glyphosate-Tolerant Weeds in Agricultural Systems* (Appendix G), alfalfa farming practices limit the likelihood of weed occurrence because alfalfa grown for hay is mowed, which reduces the likelihood that weeds reach their reproductive stage, and alfalfa is grown in rotation with annual crops (because of the nitrogen benefits it provides and autotoxicity limiting continuous alfalfa), which also limits both perennial and annual weed presence.

Appendix 3 of this technical report presents 24 glyphosate resistant weeds and their range and noxious status. Whether or not they are mentioned on the Roundup® herbicide label is also included. Two categories of glyphosate resistant weeds are shown: newly evolved or selected biotypes and species with known historical resistance to glyphosate. U.S. distribution maps for all 24 weeds are also presented. As mentioned for the Appendix 2 *Medicago* maps, the PLANTS database indicates that “not all populations have been documented, however, and significant gaps in the distribution shown may not be real... Remember that only native and naturalized populations are mapped.” Also, the distribution maps in Appendix 3 of this technical report do not represent glyphosate resistant biotypes. The maps are presented to give a general sense of where the plant species currently grow, which are potentially states to which glyphosate resistant biotypes could spread if conditions promoted their spread. For example, glyphosate resistant buckhorn plantain, goosegrass, junglerice, sourgrass, and wild poinsettia, have been reported in other countries, but not in North America. However, since these weeds have susceptible populations in North America, the growing conditions in North America presumably would also support glyphosate resistant biotypes. It is possible that glyphosate resistant biotypes could independently evolve from the North American populations, or foreign biotypes could be introduced to North America through human error or other unintentional routes.³⁰

The Federal Noxious Weed Act (1975) gave USDA the authority to designate plants as noxious weeds. The movement of noxious weeds in interstate or foreign commerce is prohibited except under permit. USDA can inspect, seize and destroy products, and quarantine areas, if necessary to prevent the spread of noxious weeds. Only tropical spiderwort (Benghal dayflower) is both glyphosate resistant and on the Federal noxious weed list. Several of the glyphosate resistant weeds are on at least one state’s noxious weed list. These include:

- Common ragweed
- Giant ragweed
- Johnsongrass
- Buckhorn plantain
- Bermudagrass
- Field bindweed
- Filaree
- Hemp sesbania

³⁰ Intentional introduction of noxious or herbicide resistant weeds is possible, but discussion of intentional environmental and agricultural sabotage is beyond the scope of this report.

- Morning glory
- Nutsedge
- Purslane
- Topical spiderwort (Benghal dayflower)
- Velvet leaf

Because control programs actively seek to eradicate noxious weeds, their susceptibility to herbicides and their distribution is important information for control managers. It is important to note that noxious weeds are not just weeds in agricultural systems. They are considered weeds regardless of their habitat, once they have been declared noxious in that state, county, or area. Alternative herbicides, mechanical removal, and spot burning are possible alternative control strategies for glyphosate resistant weeds.

3.1.1 *Is Alfalfa Considered a Weed?*

There is very little evidence to suggest that alfalfa is considered a weed, other than as a volunteer in agricultural settings (see USDA APHIS 2009). Monsanto corresponded with 13 weed control experts in Arizona, California, Idaho, Pennsylvania, Oregon, South Dakota, Washington, and Wisconsin (Rogan and Fitzpatrick 2004). None of the respondents considered alfalfa a weed. In South Dakota and Wisconsin it is encouraged to grow along roadsides. Alfalfa is one of the species that is controlled where bare ground is desired. Glyphosate as well as other herbicides were cited as tools for weed control in non-agricultural settings. Rogan and Fitzpatrick (2004) conclude that GT alfalfa would not be a problem weed in non-agricultural setting. There were also two situations where GT alfalfa would require extra control strategies. One is in irrigation ditches with running water in regions of California where the only approved herbicide for that location is glyphosate. In these situations mechanical weed removal or spot burning was recommended. Another situation that is more related to volunteer alfalfa, is alfalfa on land rotated to fruit trees. In this situation, Rogan and Fitzpatrick (2004) suggest that aggressive alfalfa stand termination practices be adopted for land that is rotated to fruit trees or other crops where herbicide use is limited and GT alfalfa has been grown previously. However, this strategy is prevention-based and does not address mitigation once a problem occurs.

Out of the 12 weed lists from the USDA PLANTS Database, *Medicago sativa* is only listed on one, the Southern Weed Science Society.

- Plant Protection and Quarantine. 2006. *Federal noxious weed list* (24 May 2006). USDA Animal and Plant Health Inspection Service. Washington, DC. 2pp. (104 entries)
- Assorted authors. *State noxious weed lists for 46 states*. State agriculture or natural resource departments. (661 entries)
- California Invasive Plant Council. 2006. *California Invasive Plant Inventory*. Cal-IPC Publication 2006-02 (February 2007). California Invasive Plant Council. Berkeley, California. (107 entries)
- Florida Exotic Pest Plant Council. 1999. *Invasive plant list* (19 October 1999). Florida Exotic Pest Plant Council. Florida. (134 entries)

- USDI, Geological Survey. 1999. *Information index for selected alien plants in Hawaii* (20 October 2003). Hawaiian Ecosystems at Risk Project, Biological Resources Division, Haleakala Field Station. Makawao, Hawaii. (197 entries)
- Haragan, P.D. 1991. *Weeds of Kentucky and adjacent states: a field guide*. The University Press of Kentucky. Lexington, Kentucky. 278pp. (141 entries)
- Uva, R.H., J.C. Neal, & J.M. DiTomaso. 1997. *Weeds of the Northeast*. Cornell University Press. Ithaca, New York. 397pp. (237 entries)
- Stubbendieck, J., G.Y. Friisoe, & M.R. Bolick. 1994. *Weeds of Nebraska and the Great Plains*. Nebraska Department of Agriculture, Bureau of Plant Industry. Lincoln, Nebraska. 589pp. (287 entries)
- Southeast Exotic Pest Plant Council. 1996. *Invasive exotic pest plants in Tennessee* (19 October 1999). Research Committee of the Tennessee Exotic Pest Plant Council. Tennessee. (140 entries)
- Southern Weed Science Society. 1998. *Weeds of the United States and Canada*. CD-ROM. Southern Weed Science Society. Champaign, Illinois. (411 entries)
- Hoffman, R. & K. Kearns (eds.). 1997. *Wisconsin manual of control recommendations for ecologically invasive plants*. Wisconsin Dept. Natural Resources. Madison, Wisconsin. 102pp. (75 entries)
- Whitson, T.D. (ed.) et al. 1996. *Weeds of the West*. Western Society of Weed Science in cooperation with Cooperative Extension Services, University of Wyoming. Laramie, Wyoming. 630pp. (344 entries)

The updated Southern Weed Science Society (SWSS), in collaboration with the North Central Weed Science Society, Interactive Encyclopedia of North American Weeds Version 3.0 (447 entries), includes alfalfa (NCWSS 2005). This is an updated version of the 1998 version cited above. The documentation provided by this list does not indicate why alfalfa is considered a weed. It is possible that it is included because it can be an unwanted volunteer in agricultural settings.

The author of the alfalfa segment of the SWSS Weed Identification guide has stated that alfalfa is not “an invasive weed” nor does it “displace native species,” but alfalfa does colonize disturbed areas (Brett Serviss, Docket No. 04-085-1 #480).

3.2 Use of Glyphosate in Non-Agricultural Settings

3.2.1 USDA Forest Service

The Forest Service uses glyphosate primarily in conifer release (58.2%), noxious weed control (15.5%), and site preparation (16.4%). Other minor uses (10.3%) include hardwood release, facilities maintenance, recreation improvement, right-of-way maintenance, seed orchard protection, wildlife habitat improvement, and other weed control (agricultural, aquatic, or nursery). The application rates are approximately 3.31 lb/acre for conifer release, 1.06 lb/acre for noxious weed control, and 3.34 lb/acre for site preparation. Thirty five commercial formulations of glyphosate are registered for forestry applications. In 2001, the total annual use of glyphosate by the Forest Service was approximately 44,700 pounds applied to approximately 19,000 acres, which corresponds to about 0.275 percent of the agricultural use (USDA FS 2003).

The Forest Service tracks usage by Region. The usage rates for the Regions are shown in table 3.1.³¹

Table H-2 USDA Forest Service use of Glyphosate 2001 (USDA FS 2003)

Region	Forest Area	Pounds	Pounds per Acre	Percentage of FS Use by Pounds
1	Northern	264	1.99	0.6
2	Rocky Mountain	182	0.69	0.4
3	Southwestern	3	1.00	--
4	Intermountain	261	0.64	0.6
5	Pacific Southwest	34,740	4.14	78
6	Pacific Northwest	1,706	1.70	3.8
8	Southern	3,419	0.88	7.6
9	Eastern	4,146	0.84	9.3
Total		44,721	2.35	100%

Glyphosate can be applied by directed foliar, broadcast foliar, or aerial methods. Backpack-applied directed foliar sprays are the most common method of application in Forest Service programs. In these applications, the sprayer is carried by backpack, and the glyphosate is sprayed on selected plant species. Glyphosate may also be applied by “hack and squirt” operations, in which a hatchet is used to cut open a tree exposing the cambium, and then the herbicide is applied to the tree using a squirt bottle. Hack and squirt applications are used to eliminate large trees during site preparation, rights-of-way maintenance, or conifer release procedures.

A less often used method of glyphosate application is broadcast foliar ground applications. This method involves mounting a two to six nozzle boom to a tractor or heavy-duty vehicle and applying the herbicide while driving through the selected vegetation.

Some additional methods are also occasionally used by the Forest Service. One is a cut stem application that is used to treat noxious weeds. The weed stem is cut and the herbicide is sprayed onto the cut stem. Another method is an aquatic application, in which the herbicide is sprayed onto aquatic noxious weeds. Aerial applications may be used for brown-and-burn operations.

In situations where bare ground is desired, glyphosate resistant weeds may persist after glyphosate application. However, since burning follows herbicide treatment, the resistant weeds would likely be controlled.

3.2.2 Other Glyphosate Users

As mentioned previously, 13 weed control experts did not consider glyphosate to be the only herbicide for roadside and other weed management, but it is considered among the tools that could be used. It was also mentioned that glyphosate is not particularly good at controlling non-GT alfalfa (Rogan and Fitzpatrick 2004).

³¹ FS regions do not correspond to EPA Regions or to the USDA Plant Variety Protection Office alfalfa growing regions. Also there is no Region 7 in the FS system.

The Roundup® herbicide (glyphosate) label³² includes numerous non-crop uses such as: airports, apartment complexes, Christmas tree farms, Conservation Reserve Program (CRP) areas, ditch banks, driveways, dry ditches, dry canals, fencerows, golf courses, greenhouses, industrial sites, landscape areas, lumber yards, manufacturing sites, municipal sites, natural areas, office complexes, ornamentals, parks, parking areas, pastures, petroleum tank farms and plumbing stations, plant nurseries, public areas, railroads, rangelands, recreation areas, rights-of-way, roadsides, schools, shadehouses, sod or turf seed farms, sports complexes, storage areas, substations, turfgrass areas, utility sites, warehouse areas and wildlife management sites.

Feral alfalfa is known to grow in many of the above settings, therefore it is possible that feral GT alfalfa could also survive in some of these non-crop locations. In these situations, alternative control measures would need to be adopted.

3.3 Summary of Findings

Twenty four weed species are known that either have newly evolved glyphosate resistant biotypes or have historically natural resistance to glyphosate. All 24 of these have naturalized or native populations in the U.S. (although one, Chinese foldwig, is found only in Hawaii). Thirteen of the 24 glyphosate resistant weed species are on at least one noxious weed list. Nine of the 14 newly evolved glyphosate resistant weeds have documented glyphosate resistant biotypes in the U.S. The remaining 5 have sensitive biotypes in the U.S, but glyphosate resistant biotypes have not yet been documented in the U.S.

There is very little evidence to suggest that alfalfa is considered a weed, other than as a volunteer in agricultural settings. Out of the 12 weed lists from the USDA PLANTS Database, *Medicago sativa* is only listed on one, the Southern Weed Science Society, and this listing may be due to volunteer alfalfa in cropland. Thirteen surveyed weed control experts only identified one setting, irrigation ditches in California, where GT alfalfa could not be controlled by alternative herbicides. In this case only glyphosate is approved for irrigation ditches, so mechanical removal or spot burning would be the alternative control measures.

The USDA Forest Service uses glyphosate to manage forests. Their usage is 0.275 percent of the quantity used on agricultural lands. The Roundup® herbicide label has 41 other non-crop setting listed. Many of these setting overlap with areas where feral alfalfa is found. There is a possibility that feral GT alfalfa could be found in non-crop areas. In cases where control is desired alternative control methods are available.

Appendix H-2. Literature Search

1.0 Literature Search Strategy

1.1 Purpose

The purpose of this literature search is to locate references about the potential impacts of glyphosate-tolerant weeds in non-agricultural ecosystems.

In addition, the titles retrieved for the literature search for the technical report *Effects of Glyphosate-Tolerant Weeds in Agricultural Systems* were also reviewed for applicability to non-agricultural eco-systems.

1.2 Retrieval criteria

Titles were used to indicate the subject of the paper. If the paper was not in English or indicated a geographic region outside of the U.S., it was not retrieved. Titles that seemed to focus on insect pests were not retrieved. Titles that seemed to indicate an agricultural focus were not retrieved. All titles that seemed applicable to the scope of the paper were searched for online by a professional librarian. Titles that were obtained for free and were cited include the URL in the citation. Titles that were not free access were obtained through online purchase or the use of a copy vendor, who regularly visits National Institutes of Health and National Agricultural Library to obtain references.

Descriptions of these files are available at <http://library.dialog.com/bluesheets/>.

1.4 Scope of Search

The search focused on any published references between 1980 and the present. A list of titles (below) was screened followed by screening of abstracts for relevant titles. There were no limits on language for titles but only English language publications were retrieved for evaluation. In addition, only papers relevant to the U.S. were retrieved. All titles are provided below, to demonstrate the wide range of literature available for other countries where Medicago species are naturally occurring.

1.5 Keywords

alfalfa (Medicago and Lucerne are synonyms for alfalfa) combined with the terms below

Feral

Ecogeography and distribution of wild legumes in Turkey

1998

Proceedings of International Symposium on In Situ Conservation of Plant Genetic Diversity

Since Turkey is one of the center of diversity for legumes, most of the *wild* relatives of economically important food and forage legume species consisting of Cicer, Lens, Pisum, Vicia, Lathyrus, Trifolium, *Medicago*

exist in flora. The ecogeography and distribution of *wild* legumes differ from species to species for each genus, starting from coastal habitats up to the highlands including *forests*. Within the framework of National Plant Genetic Resources Program ecogeography and distribution of *wild* legumes have been determined with systematic annual expeditions.

Structure and density of lucerne pollinating wild bee populations as affected by changing agriculture.
Proceedings of the 7th International Symposium on Pollination, Lethbridge, Alberta, Canada, 23-28 June 1996.
Publication Year: 1997

Intensive surveys on populations of *wild* bees (Apoidea) which pollinate *lucerne* were made in Hungary in the mid-fifties, late sixties and early seventies. Comparing these surveys, a dramatic change in the structure of *wild* bee populations occurred between the fifties and the sixties. The populations of some bee species have fallen, other species have remained unchanged, while the population of **Medicago** *oligoleges* has increased. The changes may be explained by changes in agricultural land usage since...increase in field size as well as an increased use of mechanical weed

control along *roadsides*, and by an increased use of herbicides on arable land. The effects are discussed in terms of seasonal occurrence for different groups of *wild* bees. It is concluded that the changes in agriculture have been favourable for some bee...

Legumes for improving irrigated *meadows*.
Proceedings of the Second Intermountain *Meadow* Symposium
Publication Year: 1984
... a number of species and varieties of forage legumes have been
evaluated in the mountain *meadows* of Colorado and Wyoming. Of these,
alsike clover is particularly well adapted to the wet...
... either naturally or artificially. Red clover is widely adapted and
yields as much forage as *alfalfa* during the first two or three years
following establishment. Thereafter, red clover begins to lose stand.
Alfalfa is one of the most persistent and productive legumes on better
drained sites. Cicer milkvetch....adapted as the above four species.
ADDITIONAL ABSTRACT: The use of Trifolium hybridum, T. pratense,
Medicago sativa, Lotus corniculatus, Onobrychis viciifolia, Coronilla
varia and Astragalus cicer
alone and in mixtures with grasses in the mountain *meadows* of Colorado
and Wyoming is reviewed. T. pratense was well adapted but did not persist

beyond 2-3 years. *M*. *sativa* was the most persistent and productive legume on well drained sites and A. cicer showed...

**Appendix I. The Potential for Gene Flow from
Glyphosate-Tolerant Alfalfa (*Medicago
sativa* L.) to Related Species**

The Potential for Gene Flow from Glyphosate-Tolerant Alfalfa (*Medicago sativa* L.) to Related Species

1.0 Introduction

The potential for hybridization and subsequent impact of hybridization between sexually compatible species in the *M. sativa* (alfalfa) complex naturalized in North America is discussed in this report. Information on the success of crosses between taxonomically related species and a survey of related species naturalized in North America indicates that there is no evidence for sexually compatible relatives of *M. sativa* growing in North America.

The *M. sativa* complex has been sexually hybridized with 12 other perennial *Medicago* species (reviewed in Section VII, Subsection E.1 of Petition Number 04-110-01p). Two reports of successful crosses between annual medics and *M. sativa* have been reported but both are disputed by academic experts. A report by Skalska et al. (1992) was identified through a recent literature search where the authors claimed success at crossing annual medics with *M. sativa*. While the results from this report are disputed, they have no relevance to potential outcrossing in North America because the annual medics are not found in North America. Reported successful crosses between *M. lupulina* (annual medic naturalized and widespread in North America) and *M. sativa* also are disputed by several experts and are reviewed in this report.

Potential environmental impacts due to outcrossing from Roundup Ready alfalfa to cultivated or feral alfalfa (free living) are considered to be no different from cultivation of conventional alfalfa. APHIS has previously reviewed information submitted to the agency by Monsanto and FGI on the weediness characteristics of Roundup Ready alfalfa and have determined that the transformation process, and insertion of the *cp4 epsps* gene cassette in events J101 and J163 have not altered the weediness potential of alfalfa. Information submitted relating to the use of glyphosate for control of feral alfalfa indicates that feral alfalfa is rarely controlled with herbicide and if controlled, glyphosate is not the herbicide of choice for control. Thus, the herbicide tolerance trait does not provide a competitive advantage to alfalfa, and other herbicides are available to control alfalfa that may be tolerant to glyphosate.

1.1 Alfalfa taxonomy and Related Species

The taxonomy of alfalfa and related species are reviewed in Section II and VII of Petition 04-110-01p (the petition). A brief summary is provided below. The taxonomy of the genus *Medicago* has been modified periodically, and numerous misclassifications and synonyms are used (see table 1 and 2 for examples of synonymy).

Medicago sativa L. belongs in the order Fabales, family Fabaceae, tribe Trifolieae, genus *Medicago*. The genus *Medicago* is very extensive, consisting of more than 60 different species; two thirds of the species are annuals and one third are perennials (Quiros and Bauchan, 1988).

Commercially cultivated alfalfa properly belongs to the *M. sativa* complex, a group of closely related subspecies that are interfertile and share the same karyotype. The most commonly

cultivated alfalfa in the world is *M. sativa* subsp. *sativa*, but subspecies *falcata* is also cultivated on a limited basis, primarily under rangeland conditions and in colder regions (e.g., Canada and Siberia). Other subspecies in the complex include subsp. *glutinosa*, subsp. *coerulea*, subsp. *x tunetana*, subsp. *x varia*, subsp. *x polychroa*, and subsp. *x hemicycla* (Quiros and Bauchan, 1988). Two other closely related species, *M. prostrata* and *M. glomerata*, can be considered capable of limited natural hybridization with alfalfa (Quiros and Bauchan, 1988). *M. prostrata* and *M. glomerata* do not occur naturally in North America (table 3). *M. glomerata* is generally listed as one parent of subsp. *x tunetana*, which occurs in North Africa (Lesins and Lesins, 1979).

Cultivated and closely related species of alfalfa originated in Asia Minor, Transcaucasia, Turkmenistan and Iran. Particularly in Europe, Asia, the Middle East, and North Africa, current native populations of members in the *M. sativa* complex, as well as other perennial *Medicago* species, exist to which cultivated alfalfa would hybridize (Sinskaya, 1961; Lesins and Lesins, 1979; Ivanov, 1988). Based on a search for *Medicago* populations in the United States (<http://www.natureserve.org/explorer>) 14 matches were found (see table 4). All of the 14 matches were to plants non-native to North America and were either conspecific to *Medicago sativa* (three) or naturally sexually incompatible with *M. sativa* complex (eleven).

1.2 Updated Literature Search of Interspecific Hybridization in *Medicago*

In October 2007, literature databases were searched (AGRICOLA, BIOSIS, CAB, Chemical Abstracts, Chemical Engineering and Biotechnology Abstracts, Life Science Abstracts, MEDLINE) to reveal any recent or historical natural cross-hybridization information for alfalfa. Literature search results as well as the search terms used are listed in Appendix I-2. The literature search identified numerous reports regarding natural and assisted attempts of hybridization within the *M. sativa* complex. Skalska et al. (1992) reported that limited seed set occurred after hand crossing of pollen from four annual medic taxa onto *M. sativa* flowers. Skalska et al. (1992) inferred that the species were therefore “crossable” (see Appendix I-2, Section 2 for Abstract English translation); however, according to an expert in alfalfa and annual medic breeding, E. Charles Brummer, Ph.D., Iowa State University (Appendix I-4, paraphrase of Personal Communication), this single report of crossing to these annual medic species is unconvincing, has not been cited subsequently in the literature, and use of the taxonomy by Skalska et al. (1992) may be incorrect. Further, the hybridization to other annual medics has never been reported elsewhere. Evolutionarily, *M. sativa* is very distant from the annual members of *Medicago*. Regardless, the annual species named by Skalska et al. (1992) do not occur in North America.

1.3 Putative *M. lupulina* X *M. sativa* Hybrids

M. lupulina (black medic) is an annual (possibly a sometimes short-lived perennial) self-pollinating species and is known to occur throughout the United States. Successful hybridizations between *M. sativa* and *M. lupulina* were reported (Southworth, 1928; Fryer, 1930; Shrock, 1943). The validity of the *M. lupulina* x *M. sativa* putative hybridization reports were not substantiated and the hybrid cross has not been repeatable, although it was attempted numerous times (Petition appendix 4). The validity of this hybridization has been disputed since at least 1972 (Lesins and Gillies, 1972; Lesins and Lesins, 1979; Turkington and Cavers, 1979;

and the petition Section VII-E.1 and Appendix 4). According to Quiros and Bauchan (1988) and McCoy and Bingham (1988), no annual species are known to naturally hybridize with *M. sativa*. Expert alfalfa breeders provided comments on this cross in the petition's Appendix 4. *Medicago lupulina* (black medic) is the species that might be of most concern within the list of 18 annual species in the U.S. *Medicago lupulina* is considered a weed in lawns and waste places and in forages because its seeds frequently contaminate forage legume seed crops. Based on recent expert testimony (Petition Appendix 4), the documented dispute of the earlier findings, and the lack of any unambiguous scientific evidence to counter the expert testimony for the past 35 years, APHIS concurs with the expert comments presented in the petition Appendix 4 that *M. lupulina* x *M. sativa* hybridization and the potential for alfalfa gene flow to such a hybrid, is non-existent or would require as yet unfound conditions to occur successfully.

1.4 Potential Impacts from Outcrossing of Lines J101 and J163 to Wild Relatives

In 2005, APHIS evaluated the potential for hybridization and gene introgression to occur from J101 and J163 to sexually compatible wild (free-living) relatives, and considered whether such introgression would result in increased weediness. As previously discussed, there is no evidence for existence of any sexually compatible, free-living or cultivated relatives of *M. sativa* in the U.S. or North America. Thus, possible movement of the transgene via pollen from events J101 and J163 to other members of the *Medicago* genus (see table 3) would not occur in the U.S., or it would only occur following the introduction and establishment of one of the compatible species in proximity to events J101 and J163 in the U.S. Movement of the transgene to plants within the *M. sativa* complex (table 1) can be expected if the plants are located relatively near each other. Having established that there are no related wild relatives in the U.S., movement of the *cp4 epsps* gene can only occur to cultivated or feral alfalfa populations. APHIS has determined that if the glyphosate tolerance trait moves from J101 and J163 to other alfalfa populations in the U.S., this will not have a significant impact for the following reasons:

- All *Medicago* species are not native to the Western Hemisphere; hence, there will be no impact on the natural genetic resources of these species from release in the United States if glyphosate-tolerant individuals did arise through intraspecific hybridization.
- Tolerance to glyphosate would not confer any competitive advantage to these plants unless challenged by glyphosate. This would only occur in managed ecosystems where glyphosate is applied for broad-spectrum weed control or in plant varieties developed to exhibit glyphosate tolerance and in which glyphosate is used to control weeds. As with glyphosate-tolerant alfalfa volunteers, these individuals, should they arise and where they require control, could be controlled using other available chemical and/or mechanical means.
- Undesired crosses, if they developed, would not be controlled by the use of glyphosate and control would require use of non-glyphosate vegetation management practices. Currently, glyphosate is not widely used to control unwanted alfalfa vegetation (Petition Appendix 3).

Alfalfa is not considered a serious weed, a noxious weed or an invasive species in the United States, even though feral (free-living) populations are fairly common and volunteers may occur in succeeding crops. Generally feral populations, many of which are along roadsides, are not a

problem, and generally no attempts are made to control these populations. In some instances, these feral populations are considered advantageous and are encouraged (petition Appendix 3, p. 375, 12/31/02 Letter from South Dakota State University). More detailed information concerning feral populations of alfalfa and control of feral populations is in the petition's Section E.4 (p. 287), F.3 (p. 293) and Appendix 3 (p. 369). Alfalfa is frequently used in different crop rotations, varying with the region. The use of glyphosate-tolerant alfalfa is not expected to change current crop rotation options or patterns. More detailed information on crop rotations is addressed in Section F.1 (p. 291) and Section F.4 (p. 302) of the petition. Less than 100% stand termination can result in volunteer alfalfa plants in the following crop. Therefore good stand termination procedures would still be a good method of eliminating volunteer glyphosate-tolerant alfalfa plants. More detailed information on stand termination is addressed in the petition's Section B.6 (p. 259) and specifically for glyphosate-tolerant alfalfa in Section E.2 (p. 292). If volunteers of glyphosate-tolerant alfalfa are in a crop, management practices and recommendations to control these volunteers can be found in its Sections F.3 (p. 293) and F.5 (p. 303). Based on the available information on this subject, APHIS' opinion is that alfalfa is not an important weed in the United States, but care should be taken with other GT crops that may be chosen to follow GT alfalfa.

1.5 Conclusion

On the basis of information previously provided by Monsanto and FGI and reviewed in the petition as well as information provided in this report, it is concluded that alfalfa does not naturally hybridize with any related wild relatives in North America. Thus, hybridization can only occur to cultivated or feral alfalfa populations in the United States.

Table I-3. *Medicago* Species Hybridized to Alfalfa and Their Distribution

Species	Distribution	Hybridization Method	Result ¹
<i>M. arborea</i>	Southern Europe from Canary Islands to Greece	Protoplast fusion	Viable hybrids formed between these sexually incompatible species (Nenz et al., 1996).
<i>M. cancellata</i>	Southeastern European Russia, north of Caucasus	Hand-pollination	Successful, but ploidy may interfere in crosses of certain genotypes because <i>cancellata</i> is a hexaploid.
<i>M. daghestanica</i>	Mid-mountain zone of Daghestan, Russia	Hand-pollination Ovule/embryo culture Hand-pollination using trispecies bridge	No seed produced. Successful. Alfalfa was hand crossed to a <i>daghestanica</i> x <i>pironae</i> hybrid that had been colchicine doubled to a tetraploid; resulted in hybrid seed.
<i>M. dzhawakhetica</i>	Mountains of Transcaucasia	Hand-pollination	Successful when using uneven ploidy levels. F ₁ were triploid and produced nonviable pollen. Backcrosses to alfalfa possible.
<i>M. glomerata</i>	Southern Europe to North Africa (Quiros and Bauchan, 1988)	Hand-pollination Natural	Successful Putative ancestor to subsp. x <i>tunetana</i>
<i>M. hybrida</i>	Corbier mountains and east Pyrenees	Ovule/embryo culture	Successful, no other data.
<i>M. lupulina</i>	Europe, most of Asia, North Africa, North America	Hand-pollination	DISPUTED/DISCOUNTED AS FALSE; Some reported hybrids, but contemporary experts contend they were selfed [also see Turkington and Cavers (1979)].
<i>M. marina</i>	Mediterranean and Black Sea shores, Atlantic coast of Iberia and France	Hand-pollination Ovule/embryo culture	Unsuccessful. Weak hybrids that did not produce flowers.
<i>M. papillosa</i>	Pontus mountains of north-eastern Anatolia to adjacent Caucasus mountains	Hand-pollination	Successful when using uneven ploidy levels.
<i>M. pironae</i>	Eastern Alps in northeast Italy	Ovule/embryo culture; Trispecies bridges	As for <i>daghestanica</i> , viz. ovule/embryo culture worked directly, but for hand-pollination, a trispecies bridge was required.
<i>M. prostrata</i>	Eastern Austria and Italy, eastern Adriatic coast to Greece	Hand-pollination	Successful, especially when <i>prostrata</i> is female
<i>M. rhodopea</i>	Mountain ranges of Bulgaria	Hand-pollination Ovule/embryo culture	Successful, but aberrant ploidies in progeny. Successful with normal chromosome complements.
<i>M. rugosa</i>	Mediterranean Region	Hand-pollination with embryo rescue	Single sterile plant only, no progeny produced (Piccirilli and Arcioni, 1992)
<i>M. rupestris</i>	Crimean mountains	Hand-pollination Ovule/embryo culture	Not successful. Successful, but F ₁ plants had very low fertility and backcross progeny were only produced using ovule/embryo culture.
<i>M. saxatilis</i>	Crimean mountains	Hand-pollination	Successful, particularly when alfalfa was maternal parent.
<i>M. scutellata</i>	Mediterranean region	Hand-pollination	Single plant only, no progeny produced; never replicated (Sangduen et al., 1982).

¹All data is taken from Lesins and Lesins (1979) or McCoy and Bingham (1988) unless otherwise noted. Table excludes all references to natural cross-pollination among subspecies in the *M. sativa* complex (see main text for further information).

Table I-4. Members of the Genus *Medicago* Found in North America as Listed by NatureServe Explorer.

<i>Medicago</i> sp. in North America	Evidence for Natural Hybridization to <i>Medicago sativa</i> Complex	Range of Occurrence
<i>M. arabica</i> Spotted Medic	No	CAN: BC, NB USA: AL, AR, CA, CT, DC, FL, GA, IL, LA, MA, ME, MO, MS, NC, NJ, OK, OR, PA, RI, SC, TX, VA, VT, WA
<i>M. laciniata</i> Cut-leaf Medic	No	CAN: ON USA: MA, ME
<i>M. littoralis</i> Water Medic	No	USA: NJ
<i>M. lupulina</i> Black Medic	No. Reports of hand-cross hybrids are disputed and discounted as false hybrids by numerous experts.	CAN: AB, BC, MB, NB, NF, NS, ON, PE, QC, SK USA: AK, AL, AR, AZ, CA, CO, CT, DC, DE, FL, GA, HI, IA, ID, IL, IN, KS, KY, LA, MA, MD, ME, MI, MN, MO, MS, MT, NC, ND, NE, NH, NJ, NM, NV, NY, OH, OK, OR, PA, RI, SC, SD, TN, TX, UT, VA, VT, WA, WI, WV, WY
<i>M. minima</i> Small Medic-grass	No	USA: AL, AR, AZ, CA, CT, FL, HI, KS, LA, MA, MD, MI, MO, NC, NJ, NY, OK, OR, TN, TX, VA, WA
<i>M. monspeliaca</i> Hairy Medic	No	USA: AL, ME, MD, NY
<i>M. orbicularis</i> Button Medic	No	CAN: BC, ON USA: AL, CA, FL, GA, IL, LA, MD, MS, NC, NJ, OK, TN, TX
<i>M. polymorpha</i> Toothed Medic	No	CAN: BC, NB, ON, QC, SK USA: AK, AL, AR, AZ, CA, CT, FL, GA, HI, ID, LA, MA, ME, MI, MO, MS, MT, NC, NE, NJ, NM, NV, NY, OH, OK, OR, PA, RI, SC, TN, TX, UT, VA, VT, WA, WY
<i>M. praecox</i> Mediterranean Medic	No	USA: CA, MA
<i>M. rugosa</i> Wrinkled Medic	No. A single hybrid plant was produced via hand-pollination and embryo rescue; no viable progeny produced..	USA: HI
<i>M. sativa</i> Alfalfac	Yes, Conspecific	CAN: AB, BC, MB, NB, NF, NS, ON, PE, QC, SK, YT USA: AK, AL, AR, AZ, CA, CO, CT, DC, DE, FL, GA, HI, IA, ID, IL, IN, KS, KY, LA, MA, MD, ME, MI, MN, MO, MS, MT, NC, ND, NE, NH, NJ, NM, NV, NY, OH, OK, OR, PA, RI, SC, SD, TN, TX, UT, VA, VT, WA, WI, WV, WY
<i>M. sativa</i> ssp. <i>falcate</i> Yellow Alfalfa	Yes, Conspecific	CAN: AB, BC, MB, NS, ON, PE, QC, SK USA: AK, DE, IA, IL, KS, MA, MD, MI, MN, MS, MT, ND, NE, NJ, NV, PA, SD, UT, VA, WA, WY

Appendix I-2. Literature Search

1.0 Literature Search on Interspecific Hybridization within the *Medicago* Complex

Literature databases were searched (AGRICOLA, BIOSIS, CAB, Chemical Abstracts, Chemical Engineering and Biotechnology Abstracts, Life Science Abstracts, MEDLINE) to reveal any additional recent or historical natural cross hybridization information for alfalfa. Literature search results as well as the search terms used are listed in Appendix X. The literature search confirmed that there are no sexually compatible relatives of *Medicago sativa* in North America. Thus, the risk for cross pollination and subsequent transgene introgression is limited to cultivated and feral alfalfa populations growing in North America. This information was reviewed by APHIS in Petition Number 04-110-01p, Section II (Subsection C), and Section VII (Subsection E.1).

Title

Rhizobium lusitanum sp. nov. a bacterium that nodulates *Phaseolus vulgaris*

Source

International Journal of Systematic and Evolutionary Microbiology, (2006) Vol. 56, No. 11, pp. 2631-2637. 49 ref. Publisher: Society for General Microbiology. Reading ISSN: 1466-5026 URL: <http://ijs.sgmjournals.org> DOI: 10.1099/ijs.0.64402-0

Abstract

The species *Phaseolus vulgaris* is a promiscuous legume nodulated by several species of the family Rhizobiaceae. During a study of rhizobia nodulating this legume in Portugal, we isolated several strains that nodulate *P. vulgaris* effectively and also *Macroptilium atropurpureum* and *Leucaena leucocephala*, but they form ineffective nodules in *Medicago sativa*. According to phylogenetic analysis of the 16S rRNA gene sequence, the strains from this study belong to the genus *Rhizobium*, with *Rhizobium rhizogenes* and *Rhizobium tropici* as the closest related species, with 99.9 and 99.2% similarity, respectively, between the type strains of these species and strain P1-7T. The *nodD* and *nifH* genes carried by strain P1-7T are phylogenetically related to those of other species nodulating *Phaseolus*. This strain does not carry virulence genes present in the type strain of *R. rhizogenes*, ATCC 11325T. Analysis of the *recA* and *atpD* genes confirms this phylogenetic arrangement, showing low similarity with respect to those of *R. rhizogenes* ATCC 11325T (91.9 and 94.1% similarity, respectively) and *R. tropici* IIB CIAT 899T (90.6% and 91.8% similarity, respectively). The intergenic spacer of the strains from this study is phylogenetically divergent from those of *R. rhizogenes* ATCC 11235T and *R. tropici* CIAT 899T, with 85.9 and 82.8% similarity, respectively, with respect to strain P1-7T. The tRNA profile and two-primer random amplified polymorphic DNA pattern of strain P1-7T are also different from those of *R. rhizogenes* ATCC 11235T and *R. tropici* CIAT 899T. The strains isolated in this study can be also differentiated from *R. rhizogenes* and *R. tropici* by several phenotypic characteristics. The results of DNA-DNA hybridization showed means of 28 and 25% similarity between strain P1-7T and *R. rhizogenes* ATCC 11235T and *R. tropici* CIAT 899T, respectively. All these data showed that the strains isolated in this study belong to a novel species of the genus *Rhizobium*, for which we propose the name *Rhizobium lusitanum* sp. nov.; the type strain is P1-7T (=LMG 22705T=CECT 7016T).

Title

Rhizobium daejeonense sp. nov. isolated from a cyanide treatment bioreactor

Source

International Journal of Systematic and Evolutionary Microbiology [Int. J. Syst. Evol.

Microbiol.], (20051100) vol. 55, no. 6, pp. 2543-2549. ISSN: 1466-5026.

Abstract

A polyphasic study was carried out to determine the taxonomic position of two aerobic, cyanide-degrading bacterial strains, designated L61 super(T) and L22, which had been isolated from a bioreactor for the treatment of nickel-complexed cyanide. The two isolates exhibited almost identical taxonomic characteristics. Phylogenetic analysis inferred from comparative 16S rRNA gene sequences indicated that the isolates fall in a sublineage of the genus *Rhizobium* comprising the type strains of *Rhizobium giardinii*, *Rhizobium radiobacter*, *Rhizobium rubi*, *Rhizobium larrymoorei*, *Rhizobium vitis*, *Rhizobium undicola*, *Rhizobium loessense*, *Rhizobium galegae* and *Rhizobium huautlense*. Cells of the two isolates are Gram-negative, aerobic, motile and non-spore-forming rods (0 super(.)6-0 super(.)7x1 super(.)1-1 super(.)3 μ m), with peritrichous flagella. The DNA G+C content is 60 super(.)1-60 super(.)9 mol%. Cellular fatty acids are C sub(16 : 0) (2 super(.)2-3 super(.)3 %), C sub(18 : 0) (2 super(.)1-3 super(.)2 %), C sub(19 : 0) cyclo [omega]8c (9 super(.)9-16 super(.)8 %), C sub(20 : 3)[omega]6,9,12c (2 super(.)7-3 super(.)3 %), summed feature 3 (7 super(.)2-7 super(.)7 %) and summed feature 7 (67 super(.)8- 73 super(.)7 %). The strains formed nodules on a legume plant, *Medicago sativa*. A *nifH* gene encoding denitrogenase reductase, the key component of the nitrogenase enzyme complex, was detected in L61 super(T) by PCR amplification by using a *nifH*-specific primer system. Strains L61 super(T) and L22 were distinguished from the type strains of recognized *Rhizobium* species in the same sublineage based on low DNA-DNA hybridization values (2-4 %) and/or a 16S rRNA gene sequence similarity value of less than 96 %. Moreover, some phenotypic properties with respect to substrate utilization as a carbon or nitrogen source, antibiotic resistance and growth conditions could be used to discriminate L61 super(T) and L22 from *Rhizobium* species in the same sublineage. Based on the results obtained in this study, L61 super(T) and L22 are considered to be representatives of a novel species of *Rhizobium*, for which the name *Rhizobium daejeonense* sp. nov. is proposed. The type strain is L61 super(T) (=KCTC 12121 super(T)=IAM 15042 super(T)=CCBAU 10050 super(T)). Published online ahead of print on 12 August 2005 as DOI 10.1099/ijs.0.63667-0. The GenBank/EMBL/DDBJ accession numbers for the 16S rRNA gene sequences of strains L61 super(T) and L22 are AY341343 and DQ089696, respectively. The GenBank/EMBL/DDBJ accession number for the partial *nifH* gene sequence of strain L61 super(T) is AY428644. A transmission electron micrograph of cells of strain L61 super(T), a minimum- evolution phylogenetic tree and a table detailing the fatty acid compositions of L61 super(T), L22 and related *Rhizobium* species are available as supplementary material in IJSEM Online.

Title

Variation in rDNA locus number and position among legume species and detection of 2 linked rDNA loci in the model *Medicago truncatula* by FISH

Source

Genome, (2005) Vol. 48, No. 3, pp. 556-561. 37 ref. Publisher: National Research

Abstract

Within Fabaceae, legume species have a variable genome size, chromosome number, and ploidy level. The genome distribution of ribosomal genes, easily detectable by fluorescent in situ hybridization (FISH), is a good tool for anchoring physical and genetic comparative maps. The organization of 45S rDNA and 5S loci was analysed by FISH in the 4 closely related species : *Pisum sativum*, *Medicago truncatula*, *Medicago sativa* (2 diploid taxa), and *Lathyrus sativus*. The 2 types of rDNA arrays displayed interspecific variation in locus number and location, but little intraspecific variation was detected. In the model legume, *M. truncatula*, the presence of 2 adjacent 45S rDNA loci was demonstrated, and the location of the rDNA loci was independent of the general evolution of the genome DNA. The different parameters relative to clustering of the rDNA loci in specific chromosome regions and the possible basis of rDNA instability are discussed.

Title

Methods of transforming plants and identifying parental origin of a chromosome in those plants

Source

PCT Int. Appl., 79 pp. CODEN: PIXXD2

Abstract

Methods for plant transformation, for improving transformation efficiency, and for producing transgenic plants are provided. The methods comprise crossing a recipient plant from a genetic line of a plant species of interest with a donor plant selected from a transformation competent genetic line of the same plant species or of another closely related plant species to obtain a hybrid plant. Tissues obtained from the hybrid plant are transformation competent. These tissues can then be transformed with one or more nucleotide sequences of interest and selected for transgenic events having the nucleotide sequence of interest integrated within a chromosome derived from the recipient plant. Transformed cells can be selected and transgenic hybrid plants regenerated. The nucleotide sequence of interest can be introgressed into the genetic line from which the original recipient parent was derived, or into other genetic lines. Transformed plants and seeds are addnl. provided.

Title

Development of S-SAP markers based on an LTR-like sequence from *Medicago sativa* L

Source

Molecular Genetics and Genomics, (2002) Vol. 267, No. 1, pp. 107-114. 31 ref.
Publisher: Springer-Verlag. Berlin ISSN: 1617-4615

Abstract

The Sequence-Specific Amplification Polymorphism (S-SAP) method, recently derived from the Amplified Fragment Length Polymorphism (AFLP) technique, produces amplified fragments containing a retrotransposon long terminal repeat (LTR) sequence at one end and a host restriction site at the other. We report the application of this procedure to the LTR of the Tms1 element from *M. sativa*. Genomic dot-blot analysis indicated that Tms1 LTRs represent about 0.056% of the *M. sativa* genome, corresponding to 16x10³ copies per haploid genome. An average of 66 markers were amplified for each primer combination. Overall 49 polymorphic fragments were reliably scored and mapped in a F1 population obtained by crossing diploid *M. falcata* with *M. coerulea*. The utility of the LTR S-SAP markers was higher than that of AFLP or SAMPL (Selective Amplification of Microsatellite Polymorphic Loci) markers. The efficiency index of the LTR S-SAP assay was 28.3, whereas the corresponding values for AFLP and SAMPL markers were 21.1 and 16.7, respectively. The marker index for S-SAP was 13.1, compared to 8.8 for AFLP and 9.5 for SAMPL. Application of the Tms1 LTR-based S-SAP to double-stranded cDNA resulted in a complex banding pattern, demonstrating the presence of Tms1 LTRs within exons. As the technique was successfully applied to other species of the genus *Medicago*, it should prove suitable for studying genetic diversity within, and relatedness among lucerne species.

Title

Rapid identification of Medicago nodulating strains by using two oligonucleotide probes complementary to 16S rDNA sequences.

Source

Canadian journal of microbiology, (1997 Sep) Vol. 43, No. 9, pp. 854-61. Journal code: 0372707. ISSN: 0008-4166.

Abstract

Symbiotic bacteria associated with the Medicago genus are separated into two closely related species named Sinorhizobium meliloti and Sinorhizobium medicae. To discriminate rapidly between these two bacterial species, two 15-base DNA probes, 16Smfs and 16Smed, were designed from the alignment of 16S rDNA sequences to differentiate S. meliloti from S. medicae. Their specificities were evaluated by dot-blot hybridization experiments on 25 reference strains representing 13 species of Rhizobium and Sinorhizobium, and by comparison with all 16S rDNA sequences available in the GenBank data base. No cross-reaction was found with 16Smed, which was thus considered species specific for S. medicae. By contrast, as expected according to the 16S rDNA sequence alignment, the labeled 16Smfs probe cross-hybridized with the DNAs of S. meliloti, Sinorhizobium fredii, and Sinorhizobium saheli but not with the DNA of S. medicae. Since S. saheli and S. fredii do not nodulate Medicago, 16Smed and 16Smfs can be routinely used to characterize the two Sinorhizobium species nodulating Medicago from pure cultures or from Medicago root nodules. Fifty strains isolated from eight annual Medicago species were then characterized by using colony hybridizations. Sinorhizobium meliloti was more frequently obtained (> 80% isolates) than was S. medicae. Both Sinorhizobium species seemed to be trapped by annual Medicago and no plant-host specificity was detected.

Title

Evolutionary rate variation within Mus APRT.

Source

Genome, Oct 1996. Vol. 39, No. 5. p. 914-920 Publisher: Ottawa, Ontario, Canada : National Research Council of Canada. CODEN: GENOE3; ISSN: 0831-2796

Abstract

Rodents are thought to have relatively high rates of evolution, twice as fast as the rates for mammals in other orders. However, the uniformly high rates of evolution inferred for the order Rodentia from *Mus musculus* and *Rattus norvegicus* are not consistently found for other rodent species. Using a maximum likelihood phylogenetic algorithm (DNAML), we show here that *Mus spicilegus* has a fivefold different rate of evolution in 1100 bp around the adenine phosphoribosyltransferase gene (APRT) since its divergence from a common ancestor with *Mus musculus*. A greater than threefold difference in rates is also found in a comparison of the number of evolutionary events directly detected from the APRT sequences of these two closely related *Mus* species. The evolutionary events can be directly detected, since *M. spicilegus*, *M. musculus*, and the four rodent outgroup species used to determine the ancestral sequence are so closely related. One of the major differences between *M. spicilegus* and *M. musculus* that might affect evolutionary rate is the degree of commensalism with man. The *Mus* species therefore provide a useful model for testing various hypotheses for the causes of rate variations between genes, and possibly, between lineages.

Title

Somatic hybrid plants between the forage legumes *Medicago sativa* L. and *Medicago arborea* L

Source

Theoretical and Applied Genetics, (1996) Vol. 93, No. 1/2, pp. 183-189. 30 ref. ISSN: 0040-5752

Abstract

Interspecific somatic hybrid plants were obtained by symmetrical electrofusion of mesophyll protoplasts of *Medicago sativa* with callus protoplasts of *M. arborea*. Somatic hybrid calli were picked manually from semi-solid culture medium after they were identified by their dual colour in fluorescent light. Twelve putative hybrid calli were selected and one of them regenerated plants. The morphogenesis of the somatic hybrid calli was induced by the synthetic growth regulator 1,2-benzisoxazole-3-acetic acid. Somatic hybrid plants showed intensive genome rearrangements, as evidenced by isozyme and RFLP analysis. The morphology of somatic hybrid plants was in general intermediate between the parents. The production of hybrids by protoplast fusion between sexually incompatible *Medicago* species is related to the in vitro responsiveness of the parental protoplasts. The possibility of using somatic hybrid plants in lucerne breeding is discussed.

Title

Use of RAPD analysis for in situ identification of *Ascosphaera aggregata* and *Ascosphaera larvis* in larval cadavers of the alfalfa leafcutting bee, *Megachile rotundata*.

Source

Journal of invertebrate pathology, (1996 Jul) Vol. 68, No. 1, pp. 78-83. Journal code: 0014067. ISSN: 0022-2011.

Abstract

Chalkbrood of the alfalfa leafcutting bee, *Megachile rotundata*, is caused by the fungus *Ascosphaera aggregata*. We used random amplified polymorphic DNA (RAPD) analysis for the in situ identification of *A. aggregata* and a related species, *Ascosphaera larvis*, in larval cadavers of *M. rotundata*. A simple DNA extraction method was developed to preferentially isolate DNA from fungal spores on the cadaver surface, or from ascocysts beneath the cuticle. Similar banding patterns were obtained in *A. aggregata*-infected larval cadavers from different sources and geographic areas. The RAPD banding pattern of cadavers infected with *A. aggregata* differed from that of healthy leafcutting bee prepupae. RAPD analyses of cadavers infected with *A. aggregata* and *A. larvis* resulted in similar banding profiles as those obtained from corresponding pure fungal cultures of the two species. This suggests that the RAPD bands of infected cadavers were amplified from fungal DNA, rather than from other DNA associated with the leafcutting bee cadaver. The banding patterns of "sporulating" and "non-sporulating" chalkbrood cadavers exhibited no differences; this provides the first definitive evidence that both forms of the disease result from infection with *A. aggregata*.

Title

The comparative phosphorus requirements of some temperate perennial legumes

Source

Plant and Soil, (1991) Vol. 133, No. 1, pp. 17-30. 37 ref. ISSN: 0032-079X

Abstract

P responses of *Lupinus polyphyllus*, *L. arboreus* and 7 temperate perennial pasture legumes were compared in a field trial over a range of 9 P rates, from 0 to 800 kg/ha. *Lupinus* spp. produced more than 5 t DM/ha in the absence of added P and showed no response to fertilizer. In contrast, the pasture legumes initially failed to grow without added P and responded to applications of between 200 and 800 kg/ha. At the higher P rates, DM production of pasture legumes was equivalent to that of *Lupinus* spp. In the first 2 years of the trial, the most productive pasture legume species at the higher rates of added P were also the most productive at the lower rates. P requirements for 90% of maximum yield varied greatly between species, but were closely related to maximum yield. Thus species with low P requirements for maximum yield were not necessarily P-efficient species. In the third and subsequent years of the trial *Lotus corniculatus* performed better than the other pasture legumes at the lower rates of added P. In contrast to other studies *Lotus pedunculatus* [*L. uliginosus*] showed no ability to outyield

Trifolium repens at low rates of P. Critical P concn of the pasture species for the late spring-early summer period declined in the order *T. repens* (0.34%) > *L. pedunculatus* (0.30%) > *T. pratense* (0.28%) > *T. hybridum* (0.27%) > *T. ambiguum* (0.26%) > *L. corniculatus* (0.23%). Mineralizable N levels were determined in soils under 3 species in the 7th year of the trial. At the lowest rates of added P, mineralizable N levels were much higher under *L. polyphyllus* than under *T. repens* or *L. corniculatus*. With increasing P rate, levels under the latter species increased, and at 100 kg P/ha were equivalent to those under *L. polyphyllus* with no added P.

Title

Potential use of PCR-amplified ribosomal intergenic sequences in the detection and differentiation of *Verticillium* wilt pathogens

Source

Physiological and Molecular Plant Pathology, (1991) Vol. 39, No. 1, pp. 1-11. 28 ref. ISSN: 0885-5765

Abstract

The ribosomal genes from the 2 major pathogenic species, *V. albo-atrum* and *V. dahliae*, are essentially identical, but small differences were identified in the internal transcribed spacers (ITS 1 and ITS 2) of the 2 species. A cluster of 3 non-homologous nucleotides was observed in ITS 1 and a cluster of 2 in ITS 2. These differences permitted the synthesis of oligonucleotides that hybridized differentially with the rDNA of the 2 species and allowed for an efficient, fungus-specific amplification of either DNA sequence by a polymerase chain reaction (PCR). The results illustrate the effective use of intergenic sequences for the detection of fungus in a crop such as lucerne and also suggest that PCR-amplified intergenic sequences may provide sensitive probes for the differentiation of closely related species even when the mature rRNAs are too homologous or contain no exploitable sequence differences.

Title

Immunotaxonomy of nodule-specific proteins

Source

Cytobios (1990), 61(244), 7-19 CODEN: CYTBAI; ISSN: 0011-4529

Abstract

Polyclonal antisera were prepared sep. from soluble protein exts. of nodules from 2 ureide-transporting legumes, *Glycine max* and *Sesbania exaltata*. The antisera were used to probe nodule exts. from 11 species from 6 Papilionaceae (Fabaceae) tribes. Comparison of nodule and root exts. by Ouchterlony double-diffusion, rocket immunoelectrophoresis, and Western blotting were used to identify nodule-specific

proteins (the so-called nodulins) among the species surveyed. The number of precipitin lines formed during double diffusion and rocket immunoelectrophoresis and the number of bands on Western blots of lithium dodecyl sulfate-solubilized polypeptides increased with commonality in nodule metabolism (ureide or amide transport) and similarity in nodule morphol. (determinate or indeterminate meristem). The number of precipitin lines and bands on Western blots did not necessarily increase among species considered to be taxonomically similar. LegHb, the only protein (a combination of both plant and rhizobial gene products) generally identified as common among the tribes, exhibited considerable variation in immunol. cross -reaction among the species. Very few, if any, nodule-specific proteins are common to all species nor are there any that are completely species-specific. A number of nodulins appear to be shared among metabolically similar species which are taxonomically related.

Title

Dispersed repeats and structural reorganization in subclover chloroplast DNA

Source

Molecular Biology and Evolution, (1989) Vol. 6, No. 4, pp. 355-368. 44 ref. ISSN: 0737-4038

Abstract

Gene mapping was carried out on the chloroplast DNA (ctDNA) of *Trifolium subterraneum* varieties Tallarook and Woogenellup by hybridization of cloned restriction fragments with various probes, including cloned fragments of lucerne ctDNA. The results revealed that the chloroplast genome of *T. subterraneum* contains 10 rearranged gene clusters. Eight large inversions were sufficient to explain this reorganization; however, the actual evolutionary divergence between *Trifolium* and *Medicago* may have been more complex. A fine-scale analysis of a set of ribosomal protein genes revealed insertions, deletions and transpositions. Associated with this unusually unstable genome were 2 structural features potentially involved in the rearrangements. A dispersed family of repeats, with each element about 1 kb in length, was present in at least 6 copies. A previous survey of a wide taxonomic range of species indicated that these elements are unique to the ctDNA of *T. subterraneum* and 2 closely related species. Several of the repeated elements were associated with genomic rearrangements, and 1 repeat was inserted within a normally highly conserved series of genes. It is suggested that this set of dispersed repeats may be the first family of transposable elements found in any organelle genome. In addition, the *T. subterraneum* chloroplast genome is much larger than those in other closely related legumes, even when account is taken of the presence of the repeated elements. Some of the extra DNA had no sequence similarity to other chloroplast genomes and is thought to represent insertion of DNA from another genome. These unusual features may be implicated in the rapid and major reorganization of the ctDNA in *T. subterraneum*.

Title

Effect of variation within and between *Medicago* and *Melilotus* species on the composition and dynamics of indigenous populations of *Rhizobium meliloti*

Source

Soil Biology & Biochemistry, (1988) Vol. 20, No. 1, pp. 31-38. 4 tab. 28 ref. ISSN: 0038-0717

Abstract

The effect of variation within and between legume species of the *Medicago* cross-inoculation group on the composition of populations of indigenous *Rhizobium meliloti* inhabiting nodules was evaluated with *Melilotus alba*, *Medicago lupulina* and *Medicago sativa* grown on three soils each collected from a site occupied by a long established population of one of these legumes (homologous species). Characterization of over 1400 nodule isolates on the basis of phage sensitivity revealed totals of 37, 75 and 87 distinct phage types of indigenous *R. meliloti* from the three soils, respectively. The distributions of phage types differed markedly between soils and on one soil an individual type dominated the nodule population accounting for over 60% of the isolates. The incidence and variety of phage types differed significantly between legume species grown on two of three soils indicating species variation in nodulation preferences for indigenous *R. meliloti*. Individual plants within each legume species were heterogeneous with respect to preferences for phage types although, overall, the extent of this variation differed between species and appeared related to pollination characteristics. The data indicate that the homologous legume species for a particular soil, irrespective of its pollination characteristics, consistently tended towards greater inter-plant homogeneity of nodulation preferences for indigenous *R. meliloti* than heterologous species grown on the same soil. On the basis of the evidence presented it is suggested that the legume host is an important factor determining the composition of its associated *Rhizobium* population. The implications of the results are discussed in relation to agricultural practice.

Interbreeding of *Lygus elisus* Van Duzee and *L. desertinus* Knight in the field

Source

Southwestern Entomologist, (1982) Vol. 7, No. 1, pp. 60-64. 3 ref. ISSN: 0147-1724

Abstract

The closely related species *Lygus elisus* Van D. and *L. desertinus* Knight occur on a variety of food-plants throughout western North America and are frequently found together. Studies were carried out in Arizona in 1980-81 on examples of the 2 species collected from nettleleaf goosefoot (*Chenopodium murale*) and lucerne to determine whether interbreeding occurs in the field. A high proportion (81%) of females of *L. desertinus* collected near Yuma, where the species coexists with *L. elisus*, produced offspring of both *L. desertinus* and *L. elisus* types. At Marana, near Tucson, where *L. elisus* is rare, only 17% of *L. desertinus* females produced mixed offspring. The results indicated that the 2 species are interbreeding in the Yuma area.

Development of procedures for detection and inheritance of resistance to *Phytophthora megasperma* Drechs. in diploid and tetraploid *Medicago* spp

Source

Dissertation Abstracts International, B, (1980) Vol. 41, No. 5, pp. 1589B. Order No: 8015208.

Abstract

Part of this work has been summarized elsewhere [see PBA 50, 7324]. For 58 S0 plants the correlation between mature root reaction and stem reaction to inoculation was highly significant. A similar correlation was seen in the S1 plants and F1 plants of a resistant X susceptible cross. Of 25 *Medicago* species accessions, all closely related to *M. sativa* , the most resistant were *M. coerulea* 'PI299046' and *M. falcata* 'PI377727'. The inheritance of resistance in diploid *M. sativa* 'CADL' was controlled by two dominant complementary genes, Pm1 and Pm2, while inheritance in *M. coerula* 'PI299046' was complex. In tetraploid *M. sativa* , two genetic systems conditioned resistance, viz. one in which susceptibility was incompletely dominant and the other in which the dominant complementary Pm1 and Pm2 were present. All plants from a cross of two resistant tetraploid *M. sativa* clones were resistant and this synthetic was designated WAPRS.

Source

Entomologica Scandinavica, (1980) Vol. 11, No. 4, pp. 473-480. 5 fig. 11 ref. ISSN: 0013-8711

Abstract

Aphidius eadyi sp.n., a parasite of *Acyrtosiphon pisum* (Harris) (a pest of lucerne, peas and other leguminous crops) in the West Palearctic Region, is described. Its distribution and interspecific relations (crossing experiments) to the related species *Aphidius smithi* Sharma & Subba Rao are elucidated. The new species has been found to be a promising agent for the biological control of *Acyrtosiphon pisum*, but does not parasitise the lucerne pest *A. kondoi* Shinji [see next abstract].

Genetica Agraria, (1979) Vol. 33, No. 2-4, pp. 245-268. CODEN: GEAGAC. ISSN: 0016-6685.

Abstract

Crosses ($2x \cdot 2x$, $4x \cdot 4x$ and $2x \cdot 4x$) between different *M.* species [*M. hemicycla*, *M. coerulea*, *M. falcata*, *M. sativa*, *M. gaetula*, *M. glutinosa*] were made with the purpose of studying the relationship among the species through cytogenetic analysis, the extent of homology between their chromosomes and the possible origin of the tetraploid forms. Different ploidy level was the major obstacle to successful hybridization in interspecific crosses. In fact, an induced autotetraploid showed a higher crossability with the tetraploid species than the correspondent diploid species from which it originated. All the species used, once the difference in ploidy level was eliminated, crossed rather easily and the F1 hybrids showed a good degree of fertility both as seed production by self-pollination and inter-crossing and as pollen viability; diploid species had regular meiosis, tetraploid species showed some pairing abnormalities which were also observed in the F1 hybrids, especially those from $2x \cdot 4x$ and $4x \cdot 2x$ crosses. In general, the genomes of the species examined had a good chromosome homology. The multivalent frequencies were roughly the same in *M. sativa* and *M. glutinosa*. They were higher in the other tetraploid species and in the induced autotetraploid of *M. hemicycla*. Some F1 hybrids showed much higher multivalent frequencies; the values observed were always lower than the theoretical ones; the presence of quadrivalents even with low frequency, suggests an autotetraploid origin of *M. sativa* and of the other tetraploid species studied. The results also indicate that all these species are closely related and therefore may be considered variants of 7 original species.

Title

Evaluation of a nondestructive acetylene reduction assay of nitrogen fixation for pasture legumes grown in pots.

Source

New Zealand Journal of Experimental Agriculture, (1978) Vol. 6, No. 1, pp. 65-68.
CODEN: NZJEA3. ISSN: 0301-5521.

Abstract

Plants of *Trifolium repens* L. 'Grasslands Huia' (white clover), *T. pratense* L. 'Grasslands Turoa' (Montgomery red clover), *T. hybridum* L. (alsike clover), *T. pratense* L. 'Grasslands Pawera' (broad red clover), *T. subterraneum* L. 'Tallarook' (subterranean clover), *Medicago sativa* L. 'Grasslands Wairau' (lucerne) and *Lotus pedunculatus* Cav. (synonym: *L. uliginosus* Schkuhr, *L. major* Sm) 'Grasslands Maku' (lotus) were grown in pots with adequate moisture at day/night temperatures of 15° C/10° C and 23° C/10° C, and under moisture stress at 23° C/10° C. At weekly intervals during 5 and 6 wk growth periods successive non-destructive acetylene reduction (AR) assays were performed by incubating potted plants in 5 liter plastic containers for 2 h with 200 ml acetylene. N₂ fixation over the same periods was calculated from chemical analysis of plant tissue. AR and N₂ fixation rates were closely related within species and treatments, but the molar ratio of C₂H₂ reduced: N₂ fixed differed between clovers (mean ratio 2.8:1), lucerne (3.4:1) and lotus (4.3:1). Moisture stress increased the AR:N₂ fixed ratio, but temperature had no consistent effect. Repeated assays had no effect on herbage DM [dry matter] accumulation and herbage percent N.

Title

Pachytene chromosomes of perennial *Medicago* species. II. Distantly related species whose karyotypes resemble *M. sativa*

Source

Hereditas, (1972) Vol. 72, No. 2, pp. 289-302. 20 ref. Meeting Info.: Gillies, C. B. : Pachytene chromosomes of perennial *Medicago* species. I. Species closely related to *M. sativa*.

Abstract

M. daghestanica, *M. pironae* and their sterile hybrid had similar idiograms and the two species are probably closely related. The idiograms differed from those of the *M. sativa* -*falcata*-*glutinosa* complex only in proportional lengths of the chromosomes, hence the two groups may have a common ancestor. *M. rhodopea* and *M. rhodopea* X *M. rupestris* had almost identical idiograms, leading to the conclusion that *M. rhodopea* and *M. rupestris* are closely related. The idiogram of *M. rhodopea* was very similar to that of *M. sativa*, and in a triploid hybrid between diploid *M. sativa* and autotetraploid *M. rhodopea*, trivalent pairing was observed, confirming some homology between chromosomes of the two species. The *M. sativa* group and *M. rhodopea* group may have diverged only relatively recently. "In pachytene cells of *M. rhodopea* and two of the *M. rhodopea* X *M. rupestris* hybrids, a large darkly staining body was observed in the nucleoplasm. This was shown by pyronine/methyl green staining to contain RNA, and in behaviour resembled an accessory nucleolus".

Title

Pachytene chromosomes of perennial *Medicago* species. I. Species closely related to *M. sativa*

Source

Hereditas, (1972) Vol. 72, No. 2, pp. 277-287. 26 ref.

Abstract

Pachytene chromosome complements of three diploid and one tetraploid species of perennial *Medicago* are illustrated. Caryotypic data and pachytene idiograms are presented for the diploids *Medicago coerulea*, *M. glandulosa* and *M. prostrata*. The chromosome-arm ratios and proportional lengths of the diploids are similar to published data for diploid *M. sativa*. Absolute length differences of pachytene chromosomes which occur between these species may be the result of differences in chromosome contraction. Tetraploid *M. glutinosa* has pachytene chromosomes similar in morphology to those of *M. sativa*. The presence of quadrivalents at pachytene suggested that *M. glutinosa* might be of autotetraploid origin."It is suggested that the standard pachytene idiogram for diploid *M. sativa* can be extended in use to cover all diploid species included in the *M. sativa* -*falcata*-*glutinosa* complex. Published genetic and hybridization data to support this suggestion are mentioned.

Title

Taxonomy and cytogenetics of *Medicago*

Source

Agronomy, (1972) No. 15, pp. 53-86. 58 ref. Meeting Info.: Alfalfa science and technology. ISSN: 0065-4663

Abstract

A taxonomic key comprising 62 *Medicago* taxa is given with photographs of pods and other characteristic plant parts. Special consideration is given to the *M. sativa* -*falcata*-*glutinosa* complex. Based on morphological characters of diploid *M. sativa* and *M. falcata* an attempt is made to distinguish basic taxa from those which are of hybrid origin. Chromosome numbers are listed for 60 of the taxa considered in the key. Idiograms and caryotype data based on somatic chromosome studies are given for 22 annual and two perennial species and idiograms based on pachytene chromosome studies are shown for eight perennial and five annual species. A key is given for the identification of chromosomes of an *n* set of diploid *M. sativa*. Pachytene chromosomes corresponding to this *M. sativa* complement can be recognized in species related to *M. sativa*.

Title

Trisomics in diploid alfalfa : L Production, fertility and transmission.

Source

CHROMOSOMA, (1967) Vol. 21, No. 3, pp. 232-242.

Abstract

Eight triploids were produced by pollinating male sterile alfalfa tetraploids with diploid lines of closely related "species " involving *Medicago sativa* , *M. falcata* and *M. coerulea*. Seeds were produced on all but one of the triploids by crossing them with diploid and tetraploid lines. Primary trisomic plants were obtained from the crosses with diploid lines and studies on their fertility and trisomic transmission are reported A brief review of the cytogenetic evidence indicates that the closely related "species " involved in these trisomics appear to be forms of a single polymorphic species and that cultivated tetraploid alfalfa behaves essentially as an autotetraploid. Thus, it is proposed that linkage groups established with these diploid trisomics will also represent the linkage groups of cultivated alfalfa. ABSTRACT AUTHORS: Authors

Title

Cytological studies in alfalfa polyploids.

Source

CANADIAN JOUR BOT, (1954) Vol. 32, No. 4, pp. 531-542.

Abstract

Normal tetraploid alfalfa , *Medicago sativa* L., is characterized by meiotic irregularities consisting of a low percentage of univalents, trivalents, and quadrivalents. While these irregularities might suggest an autoploid origin, their frequency is too low to be conclusive. Cytological studies of the induced octoploid and of the hexaploid, obtained from crossing tetraploid and octoploid, indicate that the two genomes in the tetraploid are only partially homologous. The partial homology is established by the meiotic behavior in the hexaploid in which a low univalent frequency indicates a correspondingly low chiasma frequency at pachytene. Nevertheless this quadrivalent frequency in the octoploid is more than three times as high as in the tetraploid which suggests a lack of complete homology between the two genomes. The theory is advanced that tetraploid species of *Medicago* originated from crosses between a series of diploid species fairly similar cytologically out differing in well marked, morphological characters. This affords an explanation for the inheritance of some characters in a disomic and others in a tetrasomic manner. Cytological and genetic evidence thus points to tetraploid alfalfa as originating as an allopolyploid from closely related diploid species. ABSTRACT AUTHORS: Auth. abst

Title

Verticillium wilt of alfalfa , background and current research.

L29 ANSWER 97 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Analytic breeding of alfalfa for resistance to Phytophthora root rot.

L29 ANSWER 98 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Registration of A169, A224, A603, A604, N.S. 31, N.S. 33, N.S. 46, and N.S. 47 broad-crowned or creeping-rooted alfalfa germplasms.

L29 ANSWER 99 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Use of meiotic analysis to describe genomic affinities in Medicago.

L29 ANSWER 100 OF 157 CABA COPYRIGHT 2007 CABI on STN DUPLICATE 38

Title

Uneven ploidy levels and a reproductive mutant required for interspecific hybridization of Medicago sativa L. X Medicago dzhawakhetica Bordz.

L29 ANSWER 101 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Influence of drought stress on genetic variances of alfalfa and wheatgrass seedlings.

L29 ANSWER 102 OF 157 CABA COPYRIGHT 2007 CABI on STN DUPLICATE 39

Title

Laboratory evaluation of medics for resistance to lucerne weevil.

L29 ANSWER 103 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Screening of Medicago species for resistance to alfalfa weevil.

L29 ANSWER 104 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Reproductive characteristics of hexaploid alfalfa derived from 3x X 6x crosses.

L29 ANSWER 105 OF 157 BIOSIS COPYRIGHT (c) 2007 The Thomson Corporation on STN

Title

IN-VITRO CULTURE OF PODS FROM ANNUAL AND PERENNIAL MEDICAGO

SPECIES.

L29 ANSWER 106 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Interspecific hybrids of perennial *Medicago* species produced via ovule-embryo culture.

L29 ANSWER 107 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Analytic breeding of alfalfa : selection and breeding at the diploid level for resistance to *Phytophthora megasperma* f. sp. *medicaginis*.

L29 ANSWER 108 OF 157 CABA COPYRIGHT 2007 CABI on STN DUPLICATE 40

Title

Sources of resistance to spotted alfalfa aphid (*Therioaphis maculata* Buckton) in medics.

L29 ANSWER 109 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Genetic variances of alfalfa and wheatgrass populations grown under water application gradients.

L29 ANSWER 110 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Interspecific hybridization of alfalfa (*Medicago sativa*) and *M. rupestris*.

L29 ANSWER 111 OF 157 CABA COPYRIGHT 2007 CABI on STN DUPLICATE 41

Title

Light and electron microscopy of embryo development in an annual X perennial *Medicago* species cross.

L29 ANSWER 112 OF 157 AGRICOLA Compiled and distributed by the National Agricultural Library of the Department of Agriculture of the United States

Title

Pollen germination and pollen tube growth following self-pollination and intra-and interspecific pollination of *Medicago* species [Includes *Medicago sativa*, alfalfa, fertilization, interspecific crosses].

L29 ANSWER 113 OF 157 BIOSIS COPYRIGHT (c) 2007 The Thomson Corporation on STN DUPLICATE 42

Title

GENETICS CYTOLOGY AND CROSSING BEHAVIOR OF AN ALFALFA
MEDICAGO -SATIVA MUTANT RESULTING IN FAILURE OF THE POST
MEIOTIC CYTOKINESIS.

L29 ANSWER 114 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Breeding alfalfa for tolerance to multiple cutting.

L29 ANSWER 115 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Description of several variants observed in plant introductions being increased at Reno,
Nevada.

L29 ANSWER 116 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Efficient hybridization of *Medicago dzhawakhetica* and *M. sativa* using a *M. sativa*
mutant lacking post-meiotic cytokinesis.

L29 ANSWER 117 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Hexaploid alfalfa derived from 3x X 6x crosses: a status report.

L29 ANSWER 118 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Testing a heterozygous block concept in advanced generations of *Medicago sativa* - *M.*
falcata hybrids.

L29 ANSWER 119 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Hybrids from diploid X tetraploid crosses in *Medicago* studied at two ploidy levels.

L29 ANSWER 120 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Studies on the breeding behavior of alfalfa, *Medicago sativa* L.: I. Selection in two
allele populations of tetraploid alfalfa. II. Mechanism of 2n egg production. III. Test of a
heterozygous block hypothesis in *M. sativa* - *M. falcata* hybrids.

L29 ANSWER 121 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Heinrichs alfalfa.

L29 ANSWER 122 OF 157 LIFESCI COPYRIGHT 2007 CSA on STN

Title

A perennial x annual *Medicago* cross.

L29 ANSWER 123 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

The inheritance of 2n pollen formation in diploid alfalfa *Medicago sativa*.

L29 ANSWER 124 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Tetrasomic segregation for multiple alleles in alfalfa.

L29 ANSWER 125 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Transfer of glandular hairs from diploid *Medicago prostrata* to tetraploid *M. sativa*.

L29 ANSWER 126 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Hybridization of crop plants.

L29 ANSWER 127 OF 157 CABA COPYRIGHT 2007 CABI on STN DUPLICATE 43

Title

Production of two species and two interspecific hybrids of *phalaris* under irrigation in south-west New South Wales.

L29 ANSWER 128 OF 157 CABA COPYRIGHT 2007 CABI on STN DUPLICATE 44

Title

Mating between *Pratylenchus penetrans* and *P. fallax* in sterile culture.

L29 ANSWER 129 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Genus *Medicago* (Leguminosae): a taxogenetic study.

L29 ANSWER 130 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Cytology and breeding of hexaploid alfalfa. I. Stability of chromosome number.

L29 ANSWER 131 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Influence of genetical and non-genetical sources of variability on number of eggs in lucerne ovaries.

L29 ANSWER 132 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Cultivated alfalfa at the diploid level: origin, reproductive stability, and yield of seed and forage.

L29 ANSWER 133 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Disease and insect resistance in cultivated grapes.

L29 ANSWER 134 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Saponins of the genus *Medicago*.

L29 ANSWER 135 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Classified list of herbage varieties England and Wales 1977/78.

L29 ANSWER 136 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Cytological analysis and electrophoretic patterns of seed proteins in *Medicago sativa*, *Medicago glutinosa* and their hybrids.

L29 ANSWER 137 OF 157 AGRICOLA Compiled and distributed by the National Agricultural Library of the Department of Agriculture of the United States

Title

Interspecific crosses between *Rhizobium leguminosarum* and *Rhizobium melioli*: Formation of haploid recombinants and of R-primes [Nodule bacteria, inoculation tests with peas and lucerne]

L29 ANSWER 138 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Attempted interspecific hybridization of *Medicago scutellata* and *M. sativa*.

L29 ANSWER 139 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Alfalfa germplasm in the United States: genetic vulnerability, use, improvement, and maintenance.

L29 ANSWER 140 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Classified list of herbage varieties in England and Wales 1976/77.

L29 ANSWER 141 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Medicago falcata L. X *M. sativa* L. (lucerne) Cv. Walkabout (Reg. Number B-8b-2).

L29 ANSWER 142 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Some factors affecting production of two species and two interspecific hybrids of *Phalaris* under irrigation.

L29 ANSWER 143 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Registration of alfalfa germplasm from cultivated X wild hybrids.

L29 ANSWER 144 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Fodder improvement in *Pennisetums*.

L29 ANSWER 145 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Polyploidy in alfalfa breeding.

L29 ANSWER 146 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Breeding lucerne (*Medicago sativa* L.) with higher tolerance to water logging.

L29 ANSWER 147 OF 157 CABA COPYRIGHT 2007 CABI on STN

Title

Reduction of chromosome number in root tip cells of *Medicago*.

Appendix I-4. Communication

1.0 Communication from E. Charles Brummer, Iowa State University, on Potential Natural Hybridization between Annual and Perennial Medics

From: ecbrummer@gmail.com [mailto:ecbrummer@gmail.com] **On Behalf Of** Charles Brummer
Sent: Tuesday, November 27, 2007 4:27 PM
To: Fitzpatrick, Sharie
Subject: Re: Annual medic X alfalfa, contd.
Hi Sharie,

You have my permission to use this letter as personal communication.

I have reviewed the Skalska et al. manuscript regarding hybridization of alfalfa with annual *Medicago* species. The limitations of the paper are significant as you describe below. I concur with all your statements below.

The major reservations I have about the paper, reiterating many that you have, are as follows:

1. Control self fertilization of the male sterile alfalfa plant to assess the potential for selfed seed production was not done--that is, the male sterility may not be complete.
2. Control hybridizations to other alfalfa (i.e., tetraploid *Medicago sativa*) plants was not done, so the potential hybridization efficiency is not noted.
3. No evidence is presented that the putative hybrids are actually hybrids and not selfs.
4. No evidence is presented that the putative hybrid seeds were viable and could germinate.

Therefore, I see no evidence in this paper that producing viable hybrids between tetraploid *M. sativa* and the annual species is possible, congruent with all previously published results that hybridization is not successful (with the exception of the Sangduen et al. paper, in which one *sativa* x *scutellata* plant was allegedly produced, but it was sterile and never replicated).

Let me know if you have other questions regarding this paper.

Best regards,

Charlie

On 11/28/07, **Fitzpatrick, Sharie** <SFitzpatrick@foragegenetics.com> wrote:

Dear Dr. Brummer:

Attached for your review are the original Skalska et al paper and the Polish to English translation of the main text. Please review in detail.

With your permission, I would intend to use your reply letter to me as a "personal communication" citation as an expert's review of this publication.

My review of the data lead me to the conclusions stated below. Please reply with your agreement, edits or other comments regarding whether or not you view the data sufficient to determine whether or not there is evidence that *Medicago sativa* produced viable hybrid progeny with any of the annual species listed and whether in your view, any other data in the literature would support these findings or discount them.

There is no evidence that seeds were viable or an attempt to germinate them; in fact "most were of dark color" and "most embryos died out" which indicate that the developed seeds were non-viable seeds. All of the data are only measurements of seed development, count, size and color.

There is no genetic evidence that putative hybrid seeds were interspecific hybrids.

There was no proper negative control (i.e., no attempt to self pollinate the *M. sativa* seed-parent plants to determine if they were fully pollen-sterile; it is known that most male sterile plants leak some viable pollen that can result in a low frequency of selfed seed of low vigor). The putative hybrid seeds may have been the result of *M. sativa* self pollination; there is no proof that they were cross-pollinated.

For all annual species, this would be the only account of interspecific hybridization between annual medics and *M. sativa* by hand pollination (with the exception of those already noted in Table II-1 from the 2004 Roundup Ready alfalfa Petition (see excerpt attached for your convenience; table summarized from published data).

Inferring from the author's closing statement that, 'the results indicate the usefulness of future research into tissue culture and cytological and biochemical methods to eliminate embryo lethality, the author's do not use their data to state that hand-crossing or natural crossing is a viable method of *M. sativa* X annual species hybridization.

Authors specifically state that hand crosses to *M. lupulina* were unsuccessful. This data supports that *M. sativa* and *M. lupulina* do not form hybrids. This supports statements made in Petition Appendix 4: "Expert Testimony of *M. sativa* with *M. lupulina*".

For perennial "species": All successful crosses were to other members of the *M. sativa* complex which is in agreement with Petition statements: i.e., *M. hemicycla*; *M. coerula*; *M. falcata*; *M. glutinosa* are synonyms for members of subspecies grouped within the *M. sativa* complex.

For the annual species listed below, this is the only account (except as noted for *M. scutellata*). Based on lack of evidence of viable hybrids, these putative hybridizations are unproven, in direct conflict with other literature, and should be discounted until proven.

M. aculeata
M. aculeata intermis
M. blanchiana
M. coronata
M. hispida

M. intertexta
M. lacininata
M. murex
M. nigra
M. orbicularus
M. rotata
M. scutellata-- previously noted by Sangduen et al., 1982; single hybrid not fertile, died out
M. truncatula

Thank you for your time.

## **Appendix J. Effects of Changes in Farming Practices on Water, Soil and Air Due to Use of Glyphosate-Tolerant Alfalfa**

# **Effects of Changes in Farming Practices on Water, Soil and Air Due to Use of Glyphosate-Tolerant Alfalfa**

## **Executive Summary**

Glyphosate-tolerant (GT) crops came on the market in 1996 and have been widely adopted since then. The primary selling feature of GT crops is the ability to apply the broad spectrum herbicide, glyphosate, directly on plants, which provides excellent weed control. Glyphosate is an attractive herbicide for farmers because it does not have restrictions regarding which crops can be planted in the field following the GT crop rotation.

### **Herbicide use associated with GT crops**

As anticipated by the developers of GT crops, the adoption of GT crops has shifted herbicide use away from many other herbicides to glyphosate and herbicide use has declined. Several analyses of pesticide use concluded that herbicide use has been reduced due to the adoption of herbicide-tolerant crops. (Brimner et al., 2005; Fernandez-Cornejo, 2006; Gianessi and Reigner, 2006; Kleter et al., 2007; Sankula, 2006; Johnson et al., 2008). One analysis of pesticide use concluded that herbicide use has increased due to herbicide-tolerant crops (Benbrook, 2004). All the studies agreed that herbicide use has shifted towards glyphosate. Using standardized methods for ranking environmental impact, researchers have concluded that glyphosate is less harmful to the environment than many other herbicides and that the shift of herbicide use has resulted in a net lower environmental impact from herbicides (Kleter et al., 2007).

### **Glyphosate occurrence in water, soil, and air**

Glyphosate adsorbs strongly to soil so doesn't generally move vertically below six inches. Glyphosate is rapidly degraded by soil microbes in the environment. The major degradate of glyphosate is aminomethyl phosphonic acid (AMPA), which degrades in the soil to form carbon dioxide. The half-life of glyphosate in soil laboratory studies is two days. In agricultural soils, the half-life of glyphosate ranges from 1.7 to 197.3 days, but is typically less than 60 days. Although glyphosate and AMPA have been detected in surface water and ground water, the concentrations are many times lower than levels where toxic effects might occur. Glyphosate has low volatility and has not been detected in air, other than possibly adhered to dust particles.

### **Non-glyphosate-tolerant, glyphosate-tolerant, and organic alfalfa**

Non-GT and GT alfalfa can be treated similarly regarding cultivation techniques and most herbicide applications. The difference between non-GT and GT alfalfa is glyphosate usage. Glyphosate can be used to remove non-GT stands, but can not be used for whole field weed control. Glyphosate can be used for in crop weed control in GT alfalfa but can not be used for stand removal. Organic farming practices do not permit the use of any herbicides. Cultivation weed control practices are permitted in organic farming.

## Herbicides associated with alfalfa farming

Herbicides related to alfalfa farming can be divided into two major groups, herbicides that do not kill alfalfa, so can be used to control weeds in alfalfa, and herbicides that kill alfalfa, so are used for stand removal. Adoption of GT alfalfa decreases the number of herbicides used to control weeds in alfalfa because glyphosate is the preferred herbicide for GT alfalfa. Adoption of GT alfalfa may increase use of some herbicides used for stand removal. For stand removal adoption of GT alfalfa may result in a shift from glyphosate to other herbicides. Herbicide shifts due to stand removal would be smaller in magnitude than herbicide shifts due to weeds control.

## Crop Rotations with alfalfa

Alfalfa is used in crop rotation because it provides nitrogen to the soil, which decreases fertilizer inputs in other rotations. Perennials and annuals promote and restrict different weeds, so rotating perennials with annuals helps control weeds in general.

Adoption of GT alfalfa affects crop rotations because glyphosate cannot be used for stand removal or volunteer alfalfa control. Therefore other herbicides, which may have rotation restrictions, may need to be used along with tillage to remove GT alfalfa stands. GT alfalfa stands may also last longer than non-GT alfalfa stands, therefore adoption of GT alfalfa may influence the number of years that alfalfa is in a rotation. It is recommended that rotations not consist of all GT crops. Because several of the crops that are popular in rotation with alfalfa (corn, soybeans) have GT varieties farmers may have to decide which GT crop provides the most benefit to the rotation plan and overall farm production.

## Companion crops

There are several types of companion cropping practices. These include crops that are interseeded with alfalfa and provide protection from wind and harsh weather or outcompete weeds in the stand establishment year, crops that are planted to cover the soil and prevent erosion between growing seasons, and barrier crops along side fields that serve as a refuge for beneficial insects and distract pests. Interseeded companion crops are not likely to be used with GT alfalfa. Mechanical and cultural methods for weed control (e.g. tillage and companion crops) were used for ~80% of the spring planted alfalfa and 18% of the fall planted alfalfa (Hower et al., 1999).

## Soil conservation

Soil conservation practices include, chiseling and subsoiling, conservation cover, conservation tillage (no-till, ridge-till, mulch till), contour farming, cover or green manure (legumes), critical area planting (erosion zones), crop residue use, filter strips, grade-stabilization structures, grass and legume in rotation, grassed waterways, strip cropping, and terracing. GT alfalfa is compatible with all soil conservation practices. GT crops are known to enhance the adoption of conservation tillage.

The cultural practices associated with GT crops and GT alfalfa have a net benefit on soil conservation and quality.

## 1.0 Introduction

Glyphosate-tolerant (GT) alfalfa is cultivated in a similar manner to conventional alfalfa, except that glyphosate can be applied “in crop” on GT alfalfa and glyphosate cannot be used for stand removal for GT alfalfa. Alfalfa, a perennial crop, can be grown for forage, seed or sprouts. This technical report discusses mainly forage (hay) alfalfa. Alfalfa grown for seed is noted where cultivation is different, for example, herbicide use is more common in seed crops than hay crops. Seed for alfalfa sprouts is not within the scope of this technical report. For a discussion of alfalfa sprouts, refer to the technical report *Glyphosate-Tolerant Alfalfa Presence in Human Food and Animal Feed* (appendix Q).

The life cycle of an alfalfa hay field includes field preparation, planting, stand establishment (first year), established stand maintenance (2-8 years), and stand termination (Orloff et al., 1997). If a crop is being harvested for hay, it is harvested multiple times per growing season, from 2-11 times depending on region. Seed crops are harvested once at the end of each growing season (Putnam et al., 2001). There are varying management practices that depend on the preference of the grower, such as harvest time, weed control method (herbicides or mowing), crop rotation, companion crop choice, insect and other pest control measures, and stand removal techniques. In general, the choice of methods can depend on the region, climate, weed spectrum, and intended market. Growers are assumed to fall into three broad categories of farming practices, conventional, GT, and organic. This technical report discusses herbicide use, tillage practices (during field preparation and stand removal), crop rotations, and companion crops for each of the three categories of farming and the effect these practices have on water, soil, and air. Insect pests and other pests (e.g., small mammals, nematodes, and diseases) may be controlled differently in organic farming versus conventional farming. However, because the use of GT alfalfa does not influence these control measures, they are not discussed in this technical report. Weed control is the only pest control for which GT alfalfa and conventional alfalfa differ.

### 1.1 Conventional Farming

Conventional farming includes any farming system where synthetic pesticides or fertilizers may be used. The definition of conventional farming usually includes the use of genetically engineered crops, but genetically engineered GT alfalfa is considered separately for this report (Harker et al., 2005). Conventional farming covers a broad scope of farming practices, ranging from farmers who only occasionally use synthetic pesticides and fertilizers to those farmers whose harvest depends on regular pesticide and fertilizer inputs.

### 1.2 GT Farming

GT alfalfa can be integrated into conventional farming practices. Farming GT alfalfa is mostly the same as farming conventional alfalfa, with a few important exceptions. Weeds can be controlled by the application of glyphosate directly on top of growing alfalfa, and, when alfalfa stands reach the end of their life cycle (typically after 3-8 years depending on growing region), glyphosate cannot be used to kill the stand to prepare for another rotation (Miller et al., 2006). In GT alfalfa, herbicides other than glyphosate, combined with tillage, are required to obtain 100 percent removal of an unwanted stand. Glyphosate can be used to prepare a field for alfalfa in

the stand establishment year. Several of the recommended GT alfalfa stand removal herbicides result in restrictions regarding what crops can be planted next, so careful crop rotation plans are necessary when using GT alfalfa.

Companion crops (usually annual grasses) are sometimes interseeded with alfalfa to provide benefits such as erosion control, protection of alfalfa seedlings from wind and frost, and reduced weed germination. The density of companion crops needs to be carefully managed, so the alfalfa seedlings do not suffer from too much competition (Orloff et al., 1997). For some farmers another important difference is that non-GT crops cannot be used as companion crops for GT alfalfa. For farmers that plant pure alfalfa stands this difference does not matter. For farmers that traditionally use companion crops, this difference is important. Companion crops can increase overall forage yield but decrease hay quality (McCordick et al., 2008).

Monsanto's Stewardship Program for GT alfalfa varieties includes the following features: 1) provides users of GT alfalfa with appropriate crop rotation practices, thereby enabling a smooth transition in and out of GT alfalfa; 2) provides vegetation control personnel (e.g., highway department personnel) with control options for feral alfalfa; 3) uses grower agreements to prevent unauthorized seed production; 4) provides the alfalfa seed production industry with gene flow information and analytical tools that will be used in the production of conventional and GT alfalfa varieties; and 5) provides Monsanto field personnel with ongoing training to address anticipated and unforeseen issues that may arise because of the introduction of the technology (Rogan and Fitzpatrick, 2004)

### 1.3 Organic Farming

For this report, organic production is only those cropping systems that fall under the USDA National Organic Program (NOP) definition of organic farming and are certified organic production systems. In organic systems, the use of synthetic pesticides, fertilizers, and genetically engineered crops is strictly limited. NOP publishes a list of approved substances for organic farming inputs (<http://www.ams.usda.gov/AMSV1.0/ams.fetchTemplateData.do?template=TemplateN&navID=NationalListLinkNOPNationalOrganicProgramHome&rightNav1=NationalListLinkNOPNationalOrganicProgramHome&topNav=&leftNav=NationalOrganicProgram&page=NOPNationalList&resultType=&acct=nopgeninfo>). GT alfalfa is not approved for use in organic systems because it is genetically engineered and because glyphosate application is not permitted in organic systems.

### 1.4 Methodology

A literature search was designed to identify peer review articles and grey literature (e.g., government reports, State Agricultural Extension Office publications) on cultivation practices in alfalfa and their effects on water, soil, and air (appendix J-2 of this technical report). Several DIALOG databases were searched. Google, Google Scholar, and Yahoo search engines supplemented the DIALOG search. Calculations for percentages of harvest were done with Microsoft Excel. Alfalfa harvest statistics were obtained from USDA's National Agricultural Statistics Service (<http://www.nass.usda.gov/index.asp>). In addition, USDA's Economics, Statistics and Market Information System (ESMIS), which is a collaborative project between

Albert R. Mann Library at Cornell University and USDA, provided information on alfalfa harvesting (<http://usda.mannlib.cornell.edu/MannUsda/homepage.do>). USDA's Agricultural Marketing Service also provided information on harvests (<http://www.ams.usda.gov>).

## 2.0 Herbicide Use in Alfalfa and GT Crops

This section discusses herbicide use on GT crops in general and in GT alfalfa. It does not discuss insecticides or genetically modified crops with traits other than glyphosate tolerance.

### 2.1 Current and Historical Herbicide Usage on GT Crops

The first GT crops were introduced in 1996. In 2007, the U.S. had the most biotech crops (herbicide and pest resistant combined) of any country (57.7 million hectares; James, 2007). Each year the International Service for the Acquisition of Agri-biotech Applications (ISAAA) publishes a report tracking global adoption of biotech crops. Figure J-1 presents the most current data. Brookes and Barfoot (2006) determined that on a global level, pesticide use has been reduced by 224 million kg of active ingredient (6.9% reduction) from 1996 to 2005.

**Figure J-1: Global biotech crop adoption (James 2007)**

USDA Economic Research Service (ERS) evaluates U.S. statistics on biotech crops and herbicide use. The primary source of data for agricultural statistics in the United States is USDA's National Agricultural Statistics Service (NASS). This report focuses on herbicide-tolerant biotech crops only. Insect resistant crops are not explicitly included. United States adoption of herbicide resistant crops in 2005 was as follows (Sankula 2006):

- Herbicide resistant canola – 93% of national acreage (62% of national acreage was GT canola, 31% was glufosinate-tolerant)
- Herbicide resistant soybean – 88% of national acreage
- Herbicide resistant cotton – 80% of national acreage
- Herbicide resistant corn – 35% of national acreage

One of the anticipated benefits of GT crops was an herbicide shift to glyphosate, which is one of the less hazardous herbicides compared to the range of herbicides that are available for weed

control. In fact this herbicide shift has been observed. Herbicide use in soybean has a high percentage of adoption (>85 % of soybeans in the U.S. in 2007 were herbicide-tolerant) and serves as an example to illustrate the shift in herbicide use (Kleter et al., 2007). Figure J-2 presents the acreage for glyphosate application and five other herbicides on soybean fields. Figure J-3 presents the change in herbicide active ingredient per hectare.

**Figure J-2: Herbicide use in soybeans, percent of total acres, 1995-2005 (Kleter, 2007)**

Use of selected herbicides on soybeans in the USA, percentage of total acreage treated with herbicides. Data from NASS,<sup>-35</sup> herbicides selected with minimally 10% acreage in 1995; no survey was carried out in 2003.

**Figure J-3: Herbicide use in soybeans, active ingredient per hectare, 1995-2005 (Kleter, 2007)**

Herbicide use on soybeans in the USA, average active ingredient per area treated with herbicides, 1995-2005. Data from NASS,<sup>-35</sup> no survey was carried out in 2003; data have been

converted to metric values employing a conversion factor of  $1 \text{ lb acre}^{-1} = 1.121 \text{ kg ha}^{-1}$ .

Overall, herbicide use in the United States shows a downward trend between 1995 and 2002, especially in corn (Fernandez-Cornejo, 2006). Figure J-4 from the USDA ERS Agricultural

Resources and Environmental Indicators (AREI) report presents herbicide application rates in corn, cotton, and soybean from 1995 to 2002.

Source: USDA, NASS surveys.

**Figure J-4: Pesticide use in major field crops  
(Fernandez-Cornejo, 2006)**

Brimner et al. (2005) evaluated herbicide use in Canada on canola from 1995 to 2000. The amount of herbicide used in conventional canola fluctuated and increased by 29.5% from 1995 to 2000. In contrast, herbicide use in herbicide resistant canola declined by 20.4% (Brimner et al., 2005).<sup>37</sup>

<sup>37</sup> Herbicide resistant canola includes imidazolinone tolerant, glufosinate tolerant, and glyphosate tolerant varieties of canola.

**Figure J-5: Herbicide active ingredient use per hectare of canola (Brimner et al., 2005)**

Benbrook (2004) evaluated the USDA NASS data on genetically modified crop acreage along with data on pesticide volumes used, from 1996 to 2004, and determined that genetically modified corn, soybeans and cotton have led to a 138 million pound increase in herbicide use since 1996, which is a 5% increase. Benbrook (2004) attributes this increase to increasing weed resistance to glyphosate and reduction in glyphosate prices after the patent expired. Benbrook (2004) concluded that across all crops, genetically modified crops reduced pesticide use from 1996 to 1998, but from 1999 to 2004, pesticide use increased. The USDA NASS data does not directly report amount of herbicide applied based on conventional versus GT varieties. NASS pesticide surveys report the percent of acres treated with a given pesticide, the average rate of application (for each distinct application), the average number of applications, the rate per crop year (average one-time rate multiplied by the number of applications), and the total pounds applied. NASS also reports total acres planted to corn, soybeans, and cotton by year, and the percent of acres planted to various genetically modified crops. Using these two sources of data, Benbrook (2004), estimated herbicide use on conventional versus herbicide resistant crops using the following equation:

$$\frac{\left[ \begin{array}{c} \text{Average herbicide rate (pounds per acre) for all acres of crop X} \\ - \\ \left[ \begin{array}{c} \% \text{ acres HT varieties for crop X} \\ \times \\ \begin{array}{c} \text{Rate herbicide application (pounds per acre) on HT crop X} \end{array} \end{array} \right] \end{array} \right]}{\begin{array}{c} \% \text{ acres non-HT varieties of crop X} \end{array}} = \begin{array}{c} \text{Herbicide Pounds Applied per Acre of Non-HT Variety of Crop X} \end{array}$$

The “rate of herbicide application in herbicide-tolerant acres” was estimated using NASS pesticide use data, coupled with information from herbicide manufacturers and universities.

At the request of Benbrook Consulting Services, USDA ERS reported for only 1998, both the percent of total soybean acreage by category (conventional varieties, no glyphosate applied; conventional varieties, glyphosate applied (mostly on no-till acreage); Roundup Ready® varieties; and other herbicide-tolerant varieties), as well as the average number of herbicides and

pounds of herbicides applied in each category. The average acre of herbicide-tolerant soybeans in 1998 was treated with 0.07 pounds more herbicide than conventional acres. Benbrook's (2004) summary is presented in figure J-6.

**Figure J-6: Annual percent change in pesticide use after introduction of genetically modified crops, 1996-2004 (Benbrook, 2004).**

Annual percent change in pesticide use brought about by herbicide-tolerant and *Bt* transgenic corn, soybeans and cotton.

Gianessi (2005) suggests additional factors besides increased weed resistance that could lead to increased herbicide use. The alternative explanations include: wet weather that may result in greater weed flushes, more no-till acres resulting in extra glyphosate applications, and lower cost of glyphosate resulting in growers increasing the rate of application to improve control of perennial weeds. Dill et al. (2008) indicate that GT corn shows a trend for increasing use of non-glyphosate herbicides, from 42 percent of acreage in 2002 to 55 percent of acreage grown in 2006.

Although Benbrook (2004) makes the case that there was a 138 million pound increase in herbicide use from 1996 to 2004, Gianessi and Reigner (2006) make the case that herbicide use decreased 61 million pounds (of active ingredient) between 1997 and 2002. Both studies used similar data sources, but Benbrook (2004) is based on only NASS data and Gianessi and Reigner (2006) used the National Pesticide Use Database (NPUD), which is based on the following:

- Surveys by the National Agricultural Statistics Service (NASS) [2,631 records]
- USDA Crop Profiles/Strategic Management Plans [657 records]
- State of California Department of Pesticide Regulation [1,054 records] - The State of California requires full reporting of pesticides used in agriculture.
- Survey of Extension Service Specialists [4,830 records]
- Other Sources [538 records] - Mint Industry Research Council, Cranberry Institute, U.S. Hop Plant Protection Committee, Oregon Hop Commission, and the New England Vegetable and Berry Growers Association. Estimates for statewide aggregations for Arizona and Nevada. Individual survey reports prepared at the state-level were available

for certain crops in several states: Nebraska, Washington, North Dakota, Georgia and Virginia.

- Assignments [567 records] - In cases where usage profiles for a crop in a state were not available from the above sources, usage estimates were assigned by assuming that a state's pesticide use profile for an active ingredient/crop combination is similar to that of a nearby state.

In cotton and soybeans between 1997 and 2002 the following herbicides were reduced, presumably replaced by glyphosate (Gianessi and Reigner, 2006):

- Bentazon reduced by 4.4 million pounds
- DSMA reduced by 0.8 million pounds
- Fluometuron reduced by 4.5 million pounds
- Imazethapyr reduced by 1.0 million pounds
- Metribuzin reduced by 1.5 million pounds
- MSMA reduced by 1.7 million pounds
- Paraquat reduced by 2.9 million pounds
- Pendimethalin reduced by 14 million pounds
- Sethoxydim reduced by 1.1 million pounds
- Trifluralin reduced by 13 million pounds

Other reductions in herbicides between 1997 and 2002 are attributed to the following (Gianessi and Reigner, 2006):

- Metolachlor was withdrawn from the market between 1997 and 2002 (1997 application was 67 million pounds). Corn growers switched to S-metolachlor which has a lower application rate than metolachlor.
- Glyphosate was adopted on many soybeans acres that were previously treated with metolachlor.
- Cyanazine was withdrawn from the market between 1997 and 2002 (1997 application was 20 million pounds). Cyanazine use in corn was replaced by glyphosate, mesotrione, rimsulfuron, and simazine.
- A 48 million reduction in corn herbicide was due to replacement of high rate herbicides (butylate, cyanazine, EPTC, metolachlor) with lower rate herbicides (flufenacet, mesotrione, rimsulfuron, S-metolachlor).

Sankula (2006) evaluated the impact of biotechnology-derived crops planted in the United States in 2005. A summary of the herbicide analysis follows:

- Herbicide-tolerant canola used less herbicide active ingredient per acre than conventional canola, which represented a reduction of 0.69 million pounds of herbicide use in 2005.
- Herbicide-tolerant corn reduced herbicide use in corn by 21.8 million pounds in 2005, which corresponds to a grower cost savings of \$269 million. Compared to 2004, grower returns were 94% higher and pesticide use was 18% lower due to a 67% increase in the adoption of herbicide resistant corn (due to EU approvals).

- Herbicide-tolerant cotton reduced pesticide use by 18 million pounds and reduced production costs by \$39 million.
- On average glyphosate-tolerant soybean programs used 1.03 pounds active ingredient per acre (lbs a.i./A) whereas conventional herbicide programs used an additional 0.32 lb a.i./A. This translates to a reduction of 39.4 million pounds of herbicide and a cost savings of \$134 million.

Johnson et al. (2008) evaluated the USDA NASS database and concluded that herbicide use in 2006 was reduced by 100.5 million pounds of active ingredient based on estimates of biotechnology-derived crop replacement of conventional crops.

## 2.2 Current Levels of Glyphosate in the Environment

### 2.2.1 *Current Levels of Glyphosate in Water*

In a U.S. Geological Survey (USGS) monitoring study of surface water, groundwater, and soil conducted from 2001 to 2006, the metabolite aminomethyl phosphonic acid (AMPA) was observed more frequently than the parent compound glyphosate (Scribner et al., 2007). The sample collections were from several USGS studies including the National Stream Quality Accounting Network Program, the National Water-Quality Assessment Program, and the Toxic Substances Hydrology Program. Additionally, glyphosate and its metabolite AMPA were found in surface water more frequently than groundwater. Higher occurrences of glyphosate and AMPA in ground and surface waters were observed when samples were taken from an area with greater proximity to agricultural areas with recent applications of glyphosate and with a recent rain event. During 2002, 171 samples were collected from 51 streams in 9 Midwestern states. Glyphosate was detected in 63 samples with a maximum concentration of 8.7 µg/L and AMPA was detected in 117 samples with a maximum concentration of 3.6 µg/L. From 2001 to 2003 water samples were collected twice a month from the Mississippi River at Baton Rouge, Louisiana. Out of the 35 samples collected, glyphosate was detected in none and AMPA was detected in 31, with a maximum concentration of 0.38 µg/L. In vernal pools glyphosate was detected in 31 of 76 samples with a maximum concentration of 328 µg/L and AMPA was detected in 30 samples with a maximum concentration of 41 µg/L. One area that had higher levels of contamination was the Leary Weber Ditch Basin, which is part of the White River Basin in Indiana. Of 117 ground water samples, glyphosate was detected in 40 samples with a maximum of 4.7 µg/L, and AMPA was detected in 85 samples with a maximum of 2.6 µg/L. Of 64 surface water samples, glyphosate was detected in 54 samples with a maximum concentration of 427 µg/L, and AMPA was detected in 52 samples with a maximum concentration of 29 µg/L. Glyphosate and AMPA were detected in 12 of 14 rainfall samples and concentrations ranged from 0.02 to 1.1 µg/L. However, this was due to glyphosate's association with particulate matter (dust), and not to its existence as vapor (Scribner et al., 2007).

Glyphosate dissipated from small forest ponds in southern Manitoba (half life of 3.5 to 11.2 days). Glyphosate and AMPA increased in sediment samples to day 36, suggesting that the sediments adsorption was a major sink (Goldsborough and Brown, 1993). In another study by the same researchers, a comparison of glyphosate dissipation from small forest ponds versus in

situ water microcosms, the half life in the ponds was 1.5 to 3.5 days and glyphosate remained at treatment levels in the water environments without soil (Goldsborough and Beck, 1989).

Major et al. (2003) studied sediments following application of glyphosate to control smooth cordgrass in marine bay environments. Their data indicate that glyphosate degradation is slower in estuarine habitats than in freshwater environments, and is more similar to degradation rates reported for agricultural soil.

In a study of the contribution of wastewater treatment plants (WWTP) to glyphosate and AMPA levels in surface waters, 40 samples were collected from upstream and down stream of 10 WWTPs and directly from effluent (Kolpin et al, 2006). Glyphosate and AMPA were detected in 67.5 percent of the samples. There was roughly a two-fold increase in the frequency of detection for both AMPA and glyphosate downstream of the WWTPs. The concentrations detected were generally low, but the maximum concentration of AMPA was 3.9 µg/L and the maximum concentration of glyphosate was 2.2 µg/L. The authors conclude that urban uses of glyphosate contribute to glyphosate and AMPA concentrations in streams (Kolpin et al., 2006). Although not stated by the authors, presumably the WWTPs served combined sewer systems, where street run off is sent to the WWTP along with waste water from drains in buildings.

Wauchope et al. (2001) used computer models to predict herbicide concentrations in surface water reservoirs under scenarios with different herbicide applications. To simulate GT corn versus non-GT corn, glyphosate and glufosinate were compared to atrazine and alachlor. In the monitoring data used to build the computer model, in almost all years, a single run-off event dominated the input into the reservoir. As a result annual herbicide concentrations were highly correlated with annual maximum daily values. Glyphosate and glufosinate loads in run-off were generally 1/5 to 1/10 those of atrazine and alachlor. The simulations indicate that if glyphosate and glufosinate completely or partially replace atrazine and alachlor there would be improvements in water quality.

Table J-1 presents a summary of the fate properties for glyphosate.

**Table J-1. Chemical Fate Properties of Glyphosate (EPA, 2006)**

| Property                                               | Value                                                                                       |
|--------------------------------------------------------|---------------------------------------------------------------------------------------------|
| Common Name                                            | Glyphosate                                                                                  |
| Chemical Name                                          | <i>N</i> -(phosphonomethyl)glycine                                                          |
| Log Kow                                                | -3                                                                                          |

A measure of pesticide persistence (half-life) and adsorption in soil ( $K_{OC}$ ) is the Groundwater Ubiquity Score (GUS), which can be calculated for pesticides in order to rank their potential to leach towards groundwater (Vogue et al., 1994).  $GUS = \log_{10}(\text{half-life}) \times [4 - \log_{10}(K_{OC})]$ , and values between 1 and 2 are low, 2 and 3 are moderate, 3 and 4 are high, and pesticides with a GUS greater than 4 has a very high potential to move toward groundwater. Glyphosate has a GUS of 1.17 with a half life of 13 days and a  $K_{OC}$  of 884, showing its low mobility and low risk of moving to groundwater. POEA (surfactant) has a GUS of 0.69 with a half life of 14 days and a  $K_{OC}$  of 2,500, showing that POEA also has very low potential to leach to groundwater. The GUS for other herbicides can be calculated from the values presented in table J-2. Glyphosate has a low vapor pressure and Henry's law constant; thus, it has a low potential to volatilize from soil and water (Vogue et al., 1994).

Table J-2 shows the results of a model that examined the environmental risks of various herbicides, all of which have low groundwater concentrations. These herbicides were evaluated in relation to glyphosate, and the relative risk gives an indication of which herbicides have greater impact on the environment. Relative risk is calculated by determining Risk Quotients (RQs), the estimated environmental concentration (based on environmental fate properties and application rates) divided by estimated concentrations in groundwater, and dividing the RQs by glyphosate's RQ. A relative risk less than one presents less risk than a relative risk greater than one. Glyphosate had less relative risk than most other active ingredients (Peterson and Hulting, 2004).

**Table J-2. Predicted Groundwater Concentrations of Active Ingredients Based on SCI-GROW Modeling (Peterson and Hulting, 2004)**

| Active Ingredient     | Application rate (g a.i./ha) | Groundwater value (ppb) | Relative Risk <sup>2</sup> | $K_{OC}$ <sup>3</sup> | Aerobic soil half-life (days) |

<sup>2</sup> Relative risk compared with glyphosate; values highlighted in grey indicate greater risk relative to glyphosate

<sup>3</sup> K<sub>OC</sub>, soil adsorption coefficient

Malone et al., (2004) tested the preferential flow of several herbicides after simulated rainfall using USDA-ARS maintained lysimeters. The lysimeters have 8.1 m<sup>2</sup> in surface area, 2.4 meters deep and wall strips to prevent side wall leakage. Collection pans collect percolate that is directed to a collection tank. The researchers found that because of preferential flow, the breakthrough time of herbicides was independent of their sorptive properties, but the transport time was dependent on the herbicide sorptive properties. Although rapid glyphosate transport occurred through preferential flow (macropore flow), glyphosate was not detected in percolate samples. None of the concentrations were close to the glyphosate EPA Maximum Contaminate Level (Malone et al., 2004).

Fomsgaard et al. (2003) also studied leaching of pesticides through soil using lysimeters. Normal till and low-till conditions were maintained for 2 years, with one initial glyphosate application corresponding to 0.8 kg active ingredient per ha. The mean yearly concentration of leached glyphosate and/or AMPA was significantly below 0.1 mg/l from both sets of lysimeters. The highest amounts of glyphosate were found in samples of leachate taken two years after spraying. The concentrations of residual AMPA in the soil were significantly higher in the in low-tillage soil than in normal-till soil. The reason for these higher concentrations could be differences in extraction efficiency and/or residuals from prior experiments that had more frequent sprayings with Round Up in the low-tillage soil (Fomsgaard et al., 2003).

Another Danish study at agricultural fields determined that leaching of glyphosate was mainly governed by pronounced macropore flow during the first months after application. Also AMPA was frequently detected more than 1.5 years after application (Kjaer et al., 2005).

Torstensson et al., (2005) glyphosate and AMPA mobility on Swedish railway embankments and found that most of the glyphosate and AMPA was found in the upper 30 cm layer of soil and the half life was less than 5 months, except for some sites where half life was longer. The experimental design also included groundwater sampling. Based on the finding that transport to groundwater is dependent on application rate, the authors concluded that Roundup Bio application rate should not exceed 3 L/ha.

In summary (Borggaard and Gimsing, 2007), groundwater and surface water contamination by glyphosate is limited because of sorption onto variable-charged soil minerals and microbial degradation. Glyphosate leaching is mainly determined by soil structure and rainfall, while leaching to drainage systems occurs due to preferential flow in macropores. In contrast, other herbicides are often found in groundwater (Kolpin et al., 1998).

## 2.2.2 Current Levels of Glyphosate in Soil

Glyphosate adsorbs strongly to soil and is not expected to move vertically below the six inch soil layer; residues are expected to be immobile in soil (Cerdeira and Duke, 2006; EPA, 2006; Vereecken, 2005). Glyphosate is primarily and rapidly degraded by soil microbes in the environment. The major degradate of this process is aminomethyl phosphonic acid (AMPA), which further degrades in the soil to form carbon dioxide. The half-life of glyphosate in soil laboratory studies is two days (EPA, 2006). In agricultural soils, the half-life of glyphosate ranges from 1.7 to 197.3 days, but is typically less than 60 days, and one study determined the disappearance time for 50 percent ( $DT_{50}$ ) to be 13 days following a single application of glyphosate (Giesy et al., 2000).  $DT_{50}$  depends on climate, weather and application rates, but in general, glyphosate will continue to degrade even after multiple applications. AMPA was found to have a longer half life than glyphosate, and it has the potential to accumulate in the soil after extensive glyphosate applications (Cerdeira and Duke, 2006).

Polyethoxylated alkyl amine (POEA) is a class of surfactants used with glyphosate to increase the plant uptake of the glyphosate. Microbial degradation is the primary degradation process for POEA as well, and the half-life for POEA in soil is estimated at 7-14 days (Giesy et al., 2000). Glyphosate and POEA have similar dissipation rates, so accumulation of POEA in the soil is not anticipated with increased glyphosate use. Both toxicity and concentration of POEA in experimental water microcosms decreases more rapidly in the presence of sediment, higher total organic carbon, clay, and microbial biomass (Wang et al., 2005).

Soil microbes readily metabolize glyphosate into AMPA and other metabolites (USDA FS, 2003). Microorganisms produce aromatic amino acids through the shikimate pathway, similar to plants. Since glyphosate inhibits this pathway, it could be expected that glyphosate would be toxic to microorganisms. However, field studies show that glyphosate has little effect on soil microorganisms, and, in some cases, field studies have shown an increase in microbial activity (USDA FS, 2003). The addition of microbes via compost made from organic solid waste did not enhance glyphosate degradation in soils (Getenga and Kengara, 2004). In one study the population size of *Pseudomonas* spp. bacteria was highly correlated with high mineralization rates of glyphosate. In addition the mineralization rates were higher in soil sampled from organically managed soils than in soil from conventional farming (Gimsing et al., 2004). In a field study on GT versus non-GT crops, soil microbial community structure based on total fatty acid methyl ester analysis indicated a significant effect of GT crop following 5 years of continuous GT crop as compared with the non-GT crop system (Locke et al., 2008). The effect of glyphosate on soil biota is discussed more in the Technical report *Potential Impacts to Wildlife, Amphibians, Plants, And Ecosystems from Increased Glyphosate and Other Chemical Usage* (appendix N).

Due to glyphosate and AMPA's strong adsorptive characteristics, they are not likely to leach to groundwater from the soil, and compared to most herbicides, leaching is very limited (Cerdeira and Duke, 2006; Grunewald et al., 2001). Studies indicate that glyphosate leaching is dominated by preferential flow mechanisms and that it is dependent on the clay particles, iron oxides and organic matter present in the soil (Vereecken, 2005). Glyphosate and its metabolite adsorb to soil particles that become suspended in runoff water and can potentially contaminate surface waters as a result of erosion of this soil. Once in surface water, glyphosate and AMPA are not

readily broken down by water or sunlight (EPA, 1993), but can be removed through standard water purification processes and disinfection processes such as ozonation and chlorination (Speth, 1994). There is also evidence that glyphosate is translocated through plants from foliar application to roots to soil (Laitinen et al., 2007).

The U.S. Geological Survey (USGS) study that monitored glyphosate and AMPA in ground water, surface water, and rainfall, also monitored soil at the Leary Weber Ditch Basin site (Scribner et al., 2007). Of 193 soil cores, glyphosate was detected in 119 with a maximum concentration of 476 µg/kg, and AMPA was detected in 154 with a maximum concentration of 956 µg/kg. For the soil samples, the maximum level of AMPA measured was 23 µg/kg, and it was detected prior to application of glyphosate (April). The authors suggest it persisted from the previous year.

Studies show that glyphosate does not move deep into the soil, it does not get transported at high levels to or through groundwater, and it does not persist long in the soil (Major, 2003; Miller et al., 1995; Torstensson, 2005). It is highly adsorptive and remains in the soil until mineralizing bacteria breaks it down into AMPA (Gimsing et al., 2004).  $K_f$  (from table J-3) is a measure of adsorption that relates the concentration of the solute on the surface to the concentration of the solute in the liquid with which it is in contact (Vereecken, 2005). It is a constant, and the higher the value of  $K_f$  is, the more immobile the glyphosate in the soil. Soil composition does have an effect on glyphosate adsorption, with presence of minerals increasing adsorption (lessening movement of the glyphosate) and the presence of soil organic matter inhibits adsorption (Getenga and Kengara, 2004; Vereecken, 2005). Table J-3 presents parameters for glyphosate adsorption in different soils. The Freundlich Equation is an adsorption isotherm, or a curve relating the concentration of a solute on the surface of an adsorbent to the concentration of the solute in the liquid with which it is in contact. The equation is defined by:

$$c_s = K_f * c^n$$

Where  $K_f$  is the Freundlich adsorption constant (a constant for a given adsorbate at a particular temperature, related to sorbent capacity) and “n” is the Freundlich exponent related to the degree of deviation from isotherm linearity (Lee et al., 2001).

**Table J-3. Freundlich Parameters of Glyphosate Adsorption in Different Soils. (Vereecken, 2005)**

| Soil Type         | C (%) | Sand (%) | Silt (%) | Clay (%) | pH   | n    | K <sub>f</sub> |
|-------------------|-------|----------|----------|----------|------|------|----------------|
| Clay Loam         | 1.56  | 9.9      | 37.5     | 52.6     | 7.5  | 0.67 | 76             |
| Silt Loam         | 2.60  | 42.29    | 44.71    | 13       | 5.96 | 0.83 | 88.97          |
| Sandy Loam        | 3.35  | 79.99    | 12.63    | 8.51     | 6.1  | 0.81 | 75.95          |
| Sandy Silt        | 3.7   | 46       | 37       | 17       | 5.8  | 0.77 | 40.64          |
| Loamy Silt        | 0.5   | 2        | 82       | 16       | 8.3  | 0.44 | 152.9          |

| Sandy Soil        | 3.1   | 90       | 2.9      | 4        | 5.32 | 0.79 | 57             |

Mamy et al., (2005) studies the environmental fate of five herbicides. The main dissipation pathways were mineralization for glyphosate and sulcotrione, volatilization for trifluralin and non-extractable residues formation for metazachlor and metamitron. All five herbicides had low persistence, and glyphosate had the shortest half-life, which varied with soil type. Trifluralin had the longest half-life. Glyphosate, metazachlor and sulcotrione were degraded into persistent metabolites. At 140 days after herbicide applications, the amounts of glyphosate and AMPA in soils were the lowest in two soils, but not in the third soil, a loamy sand with low pH. The authors concluded that the environmental advantage in using glyphosate due to its rapid degradation is counterbalanced by accumulation of AMPA specifically in the context of extensive use of glyphosate (Mamy et al., 2005).

### 2.2.3 Current Levels of Glyphosate in Air

Herbicides can pollute air either through drift, the movement of herbicide through the air to unintended sites, or volatility, evaporation into the air. Glyphosate is essentially not volatile at 25°C and has not been reported as an atmospheric contaminant (Cerdeira and Duke, 2006). When glyphosate is applied directly to plant leaves, the risk of drift is low, but when glyphosate is applied broadly to a field, the risk of drift increases (Owen, 1998). Glyphosate poses very little risk of contaminating air, but as its use increases, the opportunity for drift and application to unintended sites can increase. Glyphosate concentrations found in a few rainwater samples were considered due to glyphosate's association with particulate matter in the air (dust), and not to its existence as vapor (Scribner et al., 2007). Bennett et al. (2004) performed a life-cycle assessment on the impacts of sugar beets (both conventional and GT) on the air and environment, and found that growing GT sugar beets is less harmful to the environment than growing conventional sugar beets due to the lower emissions from herbicide manufacturers, transport and field operations. The use of glyphosate as a post-emergence herbicide leads to an increase in no-till farming, which can lead to a decrease in tractor use. No-till also decreases dust, which improves air quality. Emissions related to global warming, ozone depletion, summer smog and carcinogenicity, among others, were found to be lower in GT crop systems than conventional systems (Bennett et al., 2004).

## 2.3 Environmental Effects of Herbicides Used on GT Crops

The use of herbicides impacts the environment in multiple ways. In this report, the focus is the impact of herbicides on the soil, water and air. However, a general Environmental Impact Quotient (EIQ) was devised in 1992 that gives an indication of the effect of an herbicide on the environment in general (Kovach et al., 1992). It is calculated from the following parameters and is the average of the farm worker, consumer and ecological components:

$$EIQ = \{C[(DT*5)+(DT*P)] + [(C*((S+P)/2)*SY)+(L)] + [(F*R)+(D*((S+P)/2)*3)+(Z*P*3)+(B*P*5)]\} / 3$$

DT = dermal toxicity, C = chronic toxicity, SY = systemicity, F = fish toxicity, L = leaching potential, R = surface loss potential, D = bird toxicity, S = soil half-life, Z = bee toxicity, B = beneficial arthropod toxicity, P = plant surface half-life (Kovach, 1992).

EIQs are universal indicators, updated annually, that effectively integrate various environmental impacts of individual pesticides into a single value that is consistent and comprehensive. EIQs have been calculated by Kovach for common herbicide ingredients, and table J-4 lists the herbicides relevant to alfalfa cultivation and their EIQs (Kovach, et al., 2007).

**Table J-4. Calculated EIQs for Alfalfa-Related Herbicides (Kovach et al., 2007)**

| Herbicide                     | EIQ   |
|-------------------------------|-------|
| 2,4-D*                        | 18.67 |
| Atrazine (Atrazine)*          | 22.9  |
| Bromoxynil (Buctril)          | 20.0  |
| Clethodim (Prism, Select)     | 17.0  |
| Clopyralid (Stinger)*         | 18.1  |
| Dicamba (Dicamba)*            | 28.0  |
| Diflufenzopyr (Distinct)*     | 17.5  |
| Diuron (Karmex, Direx)        | 20.5  |
| EPTC (Eptam)                  | 9.4   |
| Glufosinate-ammonium (Rely)*  | 28.25 |
| Glyphosate (Roundup)**        | 15.3  |
| Halsulfuron methyl (Sanda)*   | 17.0  |
| Hexazinone (Velpar)           | 18.0  |
| Imazamox (Raptor)             | 19.5  |
| Imazethapyr (Pursuit)         | 27.3  |
| Metribuzin (Sencor)           | 28.4  |
| Norfluzaon (Solicam)          | 18.8  |
| Paraquat (Gramoxone Inteon)   | 31.0  |
| Picloram (Pathway)*           | 18.0  |
| Primsulfuron-methyl (Beacon)* | 27.33 |
| Sethoxydim (Poast)            | 27.5  |
| Terbacil (Sinbar)             | 16.8  |
| Trifluralin (Treflan/TR-10)   | 18.8  |

\* Indicates an herbicide used for control of alfalfa, not weeds in alfalfa

**\*\* Glyphosate can be used to control alfalfa if it is non-GT and it can be used to control weeds in GT alfalfa**

The effects of GT crops other than GT alfalfa have been studied. In a study examining the Environmental Impact (EI, calculated by multiplying the EIQ of an herbicide by application rate to get an environmental impact per acre measurement) of GT canola, researchers found that on average, the environmental impact of GT canola was lower than the environmental impact of conventional canola. It appears this is the case because the herbicides used in GT canola, such as glyphosate and imazethapyrs, tend to have lower application rates than the herbicides used in conventional canola, such as ethalfluralin and trifluralin, instead of just being more environmentally benign (Brimner et al., 2005). Table J-5 presents EIQ and EI for canola in Canada.

**Table J-5. EIQ and EI per Hectare of Canola for Common Herbicides Used in 1995, 1998 or 2000<sup>1</sup> (Brimner et al., 2005)**

| Active ingredient                             | EIQ  | EI h <sup>-1</sup> |
|-----------------------------------------------|------|--------------------|
| Herbicides used in herbicide-resistant canola |      |                    |
| Glufosinate-ammonium                          | 34.3 | 10.3               |
| Glyphosate                                    | 32.4 | 8.5                |
| Imazamox                                      | 27.3 | 0.4                |
| Imazethapyr                                   | 27.3 | 0.4                |
| Herbicides used in conventional canola        |      |                    |
| Ethalfluralin                                 | 30.7 | 25.8               |
| Sethoxydim                                    | 27.5 | 4.0                |
| Trifluralin                                   | 26.8 | 21.6               |
| Clopyralid                                    | 18.0 | 2.7                |
| Ethametsulfuron-methyl                        | 16.0 | 0.2                |

<sup>1</sup> EI was determined by multiplying the EIQ for each active ingredient by the lowest recommended application rate of that ingredient in kg a.i. ha<sup>-1</sup>

Another study calculated EI for GT cotton, corn and soybean, as well as canola in the United States, and concluded that, in general, a downward trend in pesticide use was observed for transgenic crops when compared to non-transgenic crops (Kleter et al., 2007). The exception was a slight increase in herbicides applied to GT soybean, but this corresponded to an increased use of less environmentally persistent herbicides. Table J-6 shows a decrease of 25-33% in the quantities of herbicide active ingredients (a.i.) applied to GT crops versus non-GT crops in 2004 (Kleter et al., 2007).

**Table J-6. Environmental Impact of Herbicide Use in Herbicide-Resistant Transgenic Crops in the United States in 2004<sup>1</sup> (Kleter et al., 2007)**

| Item                                      | Non-transgenic | Transgenic herbicide-resistant | Difference | Difference, % |
|-------------------------------------------|----------------|--------------------------------|------------|---------------|
| <i>Herbicide-resistant canola</i>         |                |                                |            |               |
| Pesticide use (kg a.i. ha <sup>-1</sup> ) | 0.6            | 0.4                            | -0.2       | -30           |
| Total impact (EI ha <sup>-1</sup> )       | 14.8           | 8.6                            | -6.2       | -42           |
| Farm worker impact (EI ha <sup>-1</sup> ) | 8.9            | 4.1                            | -4.8       | -54           |
| Consumer impact (EI ha <sup>-1</sup> )    | 3.8            | 2.5                            | -1.3       | -35           |
| Ecology impact (EI ha <sup>-1</sup> )     | 31.8           | 19.4                           | -12.4      | -39           |
| <i>Herbicide-resistant cotton</i>         |                |                                |            |               |
| Pesticide use (kg a.i. ha <sup>-1</sup> ) | 5.4            | 3.7                            | -1.7       | -32           |
| Total impact (EI ha <sup>-1</sup> )       | 113.4          | 66.1                           | -47.4      | -42           |
| Farm worker impact (EI ha <sup>-1</sup> ) | 57.7           | 34.4                           | -23.4      | -40           |
| Consumer impact (EI ha <sup>-1</sup> )    | 33.1           | 21.7                           | -11.4      | -35           |
| Ecology impact (EI ha <sup>-1</sup> )     | 249.5          | 142.4                          | -107.1     | -43           |
| <i>Herbicide-resistant maize</i>          |                |                                |            |               |
| Pesticide use (kg a.i. ha <sup>-1</sup> ) | 3.8            | 2.5                            | -1.2       | -33           |
| Total impact (EI ha <sup>-1</sup> )       | 87.9           | 53.6                           | -34.4      | -39           |
| Farm worker impact (EI ha <sup>-1</sup> ) | 48.4           | 29.0                           | -19.3      | -40           |
| Consumer impact (EI ha <sup>-1</sup> )    | 26.2           | 16.2                           | -10.1      | -38           |
| Ecology impact (EI ha <sup>-1</sup> )     | 189.1          | 115.6                          | -73.5      | -39           |
| <i>Herbicide-resistant soybean</i>        |                |                                |            |               |
| Pesticide use (kg a.i. ha <sup>-1</sup> ) | 1.2            | 1.4                            | -0.4       | -25           |
| Total impact (EI ha <sup>-1</sup> )       | 42.8           | 17.7                           | -25.1      | -59           |
| Farm worker impact (EI ha <sup>-1</sup> ) | 29.3           | 9.2                            | -20.1      | -68           |
| Consumer impact (EI ha <sup>-1</sup> )    | 14.1           | 5.8                            | -8.4       | -59           |
| Ecology impact (EI ha <sup>-1</sup> )     | 85.0           | 38.1                           | -46.9      | -55           |

<sup>1</sup> Based on pesticide use data for 2004 from Sankula et al. (2005). Units have been converted to metric, e.g. 1 lb a.i. acre<sup>-1</sup> = 1.121 kg a.i. ha<sup>-1</sup>. The EIQ values have been multiplied by the values of the application rates expressed as kg a.i. ha<sup>-1</sup> in order to calculate the environmental impact per hectare (EI ha<sup>-1</sup>).

Researchers at Ghent University developed the pesticide occupational and environmental risk (POCER) indicator (Devos et al., 2008). POCER is a similar concept as EIQ and includes ten modules; (1) risk to pesticide operator; (2) risk to worker; (3) risk to bystander; (4) persistence in the soil; (5) risk of ground water contamination; (6) acute risk to aquatic organisms; (7) acute risk to birds; (8) acute risk to bees; (9) acute risk to earthworms; and (10) risk to beneficial arthropods. The toxicological reference values used in the effect assessment are certified endpoints defined in Annex VI of Directive 91/414/EEC. Using GT corn and non-GT corn as an example, the POCER values for glyphosate or glufosinate used alone were about one sixth less than other herbicide regimes (31 regimes were evaluated). This environmental benefit of glyphosate over other herbicides was attributed to lower potential for leaching and lower toxicity to aquatic organisms (Devos et al., 2008).

Using the above standardized methods for ranking environmental impact, researchers have concluded that glyphosate is less harmful to the environment than many other herbicides and that the shift of herbicide use has resulted in a net lower environmental impact from herbicides.

## 2.4 Herbicide Usage in Conventional Alfalfa Farming

Herbicides are used at three different phases in conventional alfalfa farming, stand establishment and established stands (to control weeds), and during stand removal to kill alfalfa.

The 16 herbicides that may be used for weed control in conventional alfalfa farming are summarized in table J-7 (based on Canevari et al., 2007; Loux et al., 2007; OMAFRA, 2008; Rogan and Fitzpatrick, 2004).

**Table J-7. Herbicides Used to Control Weeds in Conventional Alfalfa**

| Herbicide (Brand)                 | Stand Stage                                                       | Notes                                                                                                                                                             |
|-----------------------------------|-------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2,4-DB<br>(Butyrac,<br>Butoxone)  | 1-4 trifoliolate or<br>established stands                         | No harvesting or grazing allowed for 60<br>days following treatment                                                                                               |
| Benefin<br>(Balan)                | Before seeding                                                    | Not for use on soils high in organic matter                                                                                                                       |
| Bromoxynil<br>(Buctril)           | 2-4 trifoliolate                                                  | Often tank mixed with other herbicides                                                                                                                            |

|--------------------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Based on an extensive survey<sup>38</sup> performed from 1988 to 1992 herbicides are used much more often with seed fields (78.3% of total fields) than with hay fields (16.6% of total fields; 22% of acreage) (Hower et al., 1999). Mechanical and cultural methods for weed control (e.g. tillage and companion crops) were used for ~80% of the spring planted alfalfa and 18% of the fall planted alfalfa (Hower et al., 1999). Table J-8 presents data from Hower et al. (1999) on the acreage of alfalfa hay that is treated with herbicide versus cultural methods for weed control broken down by spring versus fall plantings and established stands.

---

<sup>38</sup> Data collected in the herbicide survey represented 90.1% of the 25.6 million acres produced annually from 1988-1992 as reported by the NASS.

**Table J-8. Alfalfa Hay Acreage (in thousands) Treated with Various Herbicides and Weed Management Strategies (U.S. 1988-1992) (Hower et al., 1999)**

| Percentage Cultural of U.S. Acres (Established)  | 0.06% | 0.36%     | 2.82%         | 4.53%  | 7.78%      |

The exact use of herbicide on alfalfa crops typically depends on region, weed spectrum and farmer preference, among other things. One herbicide rarely takes care of all weed control issues in a crop, and farmers usually have sequential combinations of herbicides to take care of summer and winter weeds. In California, research has shown that with the proper sequence and application rates, farmers can achieve weed-free alfalfa hay (Gianessi et al., 2002). In field experiments in southwestern Michigan, researchers found no net economic benefit to herbicide use in alfalfa establishment (Brothers and Hesterman 1991).

#### *2.4.1 Stand removal and volunteer control*

After 2-8 years alfalfa stands are usually thinning and vulnerable to weeds, so the stand is removed by killing the alfalfa by either plowing or herbicide application or both (Rogan and Fitzpatrick 2004). Herbicides that are used for stand removal or to control volunteer alfalfa (including GT alfalfa, except for glyphosate) include (Dillehay and Curran, 2006; Miller et al., 2006; Renz, 2007; Rogan and Fitzpatrick, 2004):

- 2,4-D
- Clopyralid
- Dicamba
- Dicamba and diflufenzopyr
- Glufosinate
- Glyphosate
- Primsulfuron-methyl
- Mixtures of dicamba, 2,4-D, and clopyralid
- Picloram
- Picloram and 2,4-D
- Halsulfuron and dicamba
- Acetochlor

- Acetochlor and atrazine
- Acetochlor and atrazine and dicamba
- Atrazine and dicamba
- Clopyralid and flumetsulam

See table J-11 for more detailed information on the herbicides used for alfalfa control.

## 2.5 Herbicide Usage in GT Alfalfa Farming

Glyphosate can be used for both hay and seed fields at stand establishment, in order to prepare the field for planting. The effectiveness of this first application depends on the weed species present, their germination period, and how long until the alfalfa grows big enough to compete with weeds on its own. If the application was effective, successive treatments would not be needed, but if the first application was not effective, it is possible that multiple glyphosate treatments would be needed (Canevari et al., 2007). In the technical report *Potential Impacts To Wildlife, Amphibians, Plants, And Ecosystems From Increased Glyphosate And Other Chemical Usage* (appendix N), the maximum use rate accepted for quantitative risk assessment was 1.99 lb a.e./acre for a single use, with minimum reapplication after 7 days and not to exceed 7.98 lb a.e./acre in a year. Monsanto recommends a maximum of 1.5 lb a.e./acre for a single application, with a seasonal maximum of 4.5 lb a.e./acre and a combined total of all pre-emergence and post-emergence applications of glyphosate per year of 6 lbs a.e./acre (Rogan and Fitzpatrick, 2004). Table J-9 present rates of glyphosate use on GT alfalfa based on different tillage practices (Rogan and Fitzpatrick, 2004).

**Table J-9. Typical Agronomic Practice for Glyphosate Applications to GT Alfalfa – Stand Establishment Year (Rogan and Fitzpatrick 2004)**

| Type of Application                                       | Application Rate <sup>1</sup> | Purpose                                                                                         |
|-----------------------------------------------------------|-------------------------------|-------------------------------------------------------------------------------------------------|
| No-Till Farming                                           |                               |                                                                                                 |
| Pre-plant, at planting or pre-emergence                   | Up to 1.5                     | No-till. Weed control prior to alfalfa emergence.                                               |
| Post-emergence: emergence to 4-trifoliate stage           | 0.75                          | Weed control and removal of non-Roundup Ready alfalfa seedlings (null application) <sup>2</sup> |
| Post-emergence: 5-trifoliate to 5 days prior to first cut | 0.75                          | 2 <sup>nd</sup> weed control application for heavy infestations                                 |
| <i>Combined total of all applications per year</i>        | <i>3.00</i>                   |                                                                                                 |
| Conventional Tillage                                      |                               |                                                                                                 |
| Post-emergence: emergence to 4-trifoliate stage           | 0.75                          | Weed control and removal of non-Roundup Ready alfalfa seedlings (null application) <sup>2</sup> |
| Post-emergence: 5-trifoliate to 5 days prior to first cut | 0.75                          | Weed control (annual and perennial)                                                             |
| <i>Combined total of all applications per year</i>        | <i>1.50</i>                   |                                                                                                 |

<sup>1</sup> pound per acre glyphosate acid equivalents

<sup>2</sup> Due to the biology and breeding constraints of alfalfa, up to 10% of the seedlings may not contain the Roundup Ready gene. See Appendix of Rogan and Fitzpatrick, 2004

There are specific herbicide mixtures recommended by the Roundup® label ([http://www.monsanto.com/monsanto/ag\\_products/pdf/labels\\_msds/roundup\\_orig\\_max\\_label.pdf](http://www.monsanto.com/monsanto/ag_products/pdf/labels_msds/roundup_orig_max_label.pdf)) to control various weeds of alfalfa. These weeds are either naturally resistant to glyphosate or have recently evolved resistant biotypes. For more discussion of glyphosate resistant weeds refer to the Technical report *Effects of Glyphosate-Tolerant Weeds in Agricultural Systems* (appendix G). Weeds for which mixtures are recommended include:

- Common ragweed
- Common waterhemp
- Giant ragweed
- Horseweed (Marestail)
- Italian ryegrass
- Johnsongrass
- Palmer Amaranth
- Rigid ryegrass
- Junglerice
- Burning nettle
- Cheeseweed
- Common lambsquarters
- Field bindweed
- Filaree

- Large crabgrass
- Morning glory
- Purslane
- Velvet leaf

### 2.5.1 Stand Removal and volunteer control

Glyphosate can be used to kill old stands of conventional alfalfa for crop rotations, however, GT alfalfa has to be removed through other mechanisms. Application of an herbicide (e.g., 2,4-D, dicamba (Banvel®), and clopyralid (Stinger®)) and tillage is effective. In no-till systems 2,4-D and dicamba can be applied together. However dicamba cannot be used before planting soybean (Dillehay and Curran, 2006).

Renz (2007) reported that dicamba and 2,4-D (WeedMaster®) applied at 2 pt/acre achieved zero resprouting of alfalfa in the spring following herbicide application. Lower concentrations of WeedMaster resulted in 0.3 to 2.5 percent resprouting. The other herbicides applications (dicamba or 2,4-D only) resulted in 0.5 to 26.5 percent resprouting. In another study, picloram and 2,4-D was more effective than dicamba and 2,4-D (Miller et al., 2006). Combined with plowing, clopyralid, clopyralid plus 2,4-D, dicamba plus 2,4-D, picloram, and picloram plus 2,4-D all controlled alfalfa 100 percent. Plowing alone provided 75 percent control of alfalfa (Miller et al., 2006).

Multiple other combinations of herbicides and tillage can be used for stand removal. See table J-11 for a list of these possible treatments, their effects and possible restrictions. Figure J-7 presents Monsanto's Technical User Guide stand takeout guidance.

**STAND TAKEOUT AND VOLUNTEER MANAGEMENT**

Crop rotations can be divided into two main groups, alfalfa rotated to: 1) grass crops (e.g. corn and cereal crops); and 2) broadleaf crops. More herbicide alternatives exist for management of volunteer alfalfa in grass crops. The recommended steps for controlling volunteer Roundup Ready Alfalfa are:

**Diligent Stand Takeout**

Use appropriate commercially available herbicide treatments alone for reduced tillage systems or in combination with tillage to terminate the Roundup Ready Alfalfa stand. Refer to your regional technical bulletin for specific stand takeout recommendations. NOTE: Roundup agricultural herbicides are **not** effective for terminating Roundup Ready Alfalfa stands.

**Start Clean**

If necessary, utilize tillage and/or additional herbicide application(s) after stand takeout, and before planting of the subsequent rotational crop to manage any newly emerged or surviving alfalfa.

**Plan for Success**

Rotate to crops with known and available mechanical or herbicidal methods for managing volunteer alfalfa, keeping in mind that Roundup agricultural herbicides will not terminate Roundup Ready Alfalfa stands.

- Rotations to certain broadleaf crops are not advisable if the grower is not willing to implement recommended stand termination practices.
- In the event that no known mechanical or herbicidal methods are available to manage volunteer alfalfa in the desired rotational crop, it is suggested that a crop with established volunteer alfalfa management practices be introduced into the rotation.

**Timely Execution**

Implement in-crop mechanical or herbicide treatments for managing alfalfa volunteers in a timely manner; that is, before the volunteers become too large to control or begin to compete with the rotational crop.

**Figure J-7: Monsanto technology user guide for stand removal (Monsanto, 2008)**

For stand takeout procedures, Monsanto, using information from the Crop Data Management System's (CDMS) Ag Product Label Service database, recommends 2,4-D, clopyralid (Stinger®), dicamba - dimethylamin salt (Banvel®), dicamba – diglycolamine salt (Clarity®), diflufenzopyr + dichloro-o-anisic acid (Distinct®), glufosinate (Liberty®), glyphosate (Roundup), and rimsulfuron-methyl (Beacon®) for control of alfalfa. Independent research has demonstrated that dicamba, 2,4-D, tank mixtures of dicamba and 2,4-D, and clopyralid were often more effective than glyphosate for terminating alfalfa stands (Rogan and Fitzpatrick, 2004).

In order to control volunteer alfalfa, growers currently use a combination of tillage and herbicide treatments, both prior to planting and again after crop emergence. 2,4-D, dicamba - dimethylamin salt (Banvel), dicamba - diglycolamine salt (Clarity), clopyralid (Stinger), rimsulfuron (Matrix®), primisulfuron-methyl (Beacon) and diflufenzopyr + dichloro-o-anisic acid (Distinct) are registered for in-crop use to remove volunteer alfalfa in 35 crops. They are also labeled for control of feral alfalfa in 15 non-crop settings, such as roadsides, fencerows, and ditch banks and in 22 forestry, turf or municipal settings, such as Douglas fir (*Pseudotsuga* spp.), turfgrass, or golf courses (Rogan and Fitzpatrick, 2004)

Acetochlor, acetochlor and atrazine, acetochlor, atrazine and dicamba, atrazine and dicamba, and clopyralid and flumetsulamcan herbicides and mixes can control volunteer GT alfalfa in corn (Rogan and Fitzpatrick 2004). Clopyralid is effective at controlling volunteer alfalfa in broccoli (Tickes 2002). Clopyralid or 2,4-D provide control of volunteer alfalfa in 33 different crops. Exceptions include potatoes and popcorn (Rogan and Fitzpatrick 2004).

Feral alfalfa (alfalfa not in fields) is discussed in more depth in the *technical report Effects of Glyphosate-Tolerant Weeds in Non-agricultural Ecosystems* (appendix H).

Adoption of GT alfalfa decreases the number of herbicides used to control weeds in alfalfa because glyphosate is the preferred herbicide for GT alfalfa. Adoption of GT alfalfa may increase use of some herbicides used for stand removal. For stand removal adoption of GT alfalfa may result in a shift from glyphosate to other herbicides. Herbicide use to control weeds occurs mainly in the first year during stand establishment and as needed during subsequent years of stand life. Herbicide use for stand removal occurs once during stand life-cycle, which is 2-8 years. Herbicide shifts due to stand removal would be smaller in magnitude than herbicide shifts due to weeds control.

## 2.6 Herbicide Usage in Organic Alfalfa Farming

In organic systems, where synthetic herbicides are not permitted, the area to be seeded with alfalfa is tilled and allowed to sit for seven to ten days. Two or more disking passes may be necessary if weed germination is observed. The field should also be treated with nutrients, such as compost and boron, and left for a week to check for further weed germination. Planting can occur once weed growth potential is minimized (Guerena and Sullivan, 2003). Manure fertilizer should be composted to kill weed seeds (Canevari et al., 2007). The USDA NOP standards list the following approved inputs to control weeds (<http://www.ams.usda.gov/AMSv1.0/getfile?dDocName=STELPRDC5068682&acct=nopgeninfo>):

- a) As herbicides, weed barriers, as applicable.
  - i) Herbicides, soap-based—for use in farmstead maintenance (roadways, ditches, right of ways, building perimeters) and ornamental crops.
  - ii) Mulches.
    - (1) Newspaper or other recycled paper, without glossy or colored inks.
    - (2) Plastic mulch and covers (petroleum-based other than polyvinyl chloride (PVC)).

In 1994 organic farmers used several weed control practices that are presented in figure J-8.

**Figure J-8: Weed control practices used by organic farmers to produce vegetables, 1994 (Padgitt et al., 2000)**

## 2.7 Summary of Findings

GT crops, which were introduced in 1996, have been widely adopted in the United States and their adoption in the United States and globally is on an upward trend (James, 2007).

Several analyses of pesticide use concluded that herbicide use has been reduced due to the adoption of herbicide-tolerant crops. (Brimner et al., 2005; Fernandez-Cornejo, 2006; Gianessi and Reigner, 2006; Kleter et al., 2007; Sankula, 2006; Johnson et al., 2008). One analysis of pesticide use concluded that herbicide use has increased due to herbicide-tolerant crops (Benbrook, 2004). All the studies agreed that herbicide use has shifted towards glyphosate. Using standardized methods for ranking environmental impact, researchers have concluded that glyphosate is less harmful to the environment than many other herbicides and that the shift of herbicide use has resulted in a net lower environmental impact from herbicides (Kleter et al., 2007).

Glyphosate adsorbs strongly to soil so doesn't generally move vertically below six inches. Glyphosate is rapidly degraded by soil microbes in the environment. The major degradate of glyphosate is aminomethyl phosphonic acid (AMPA), which degrades in the soil to form carbon dioxide. The half-life of glyphosate in soil laboratory studies is two days. In agricultural soils, the half-life of glyphosate ranges from 1.7 to 197.3 days, but is typically less than 60 days. Although glyphosate and AMPA have been detected in surface water and ground water, the

concentrations are many times lower than levels where toxic effects might occur. Glyphosate has low volatility and has not been detected in air, other than possibly adhered to dust particles.

Herbicides are used much more often with alfalfa seed fields (78.3% of total fields) than with hay fields (16.6% of total fields; 22% of acreage). Mechanical and cultural methods for weed control (e.g. tillage and companion crops) were used for ~80% of the spring planted alfalfa and 18% of the fall planted alfalfa (Hower et al., 1999).

Non-GT and GT alfalfa can be treated similarly regarding cultivation techniques and most herbicide applications. The difference between non-GT and GT alfalfa is glyphosate usage. Glyphosate can be used to remove non-GT stands, but can not be used for whole field weed control. Glyphosate can be used for in crop weed control in GT alfalfa but can not be used for stand removal. Organic farming practices do not permit the use of any herbicides. Cultivation weed control practices are permitted in organic farming.

Herbicides related to alfalfa farming can be divided into two major groups, herbicides that do not kill alfalfa, so can be used to control weeds in alfalfa, and herbicides that kill alfalfa, so are used for stand removal. Adoption of GT alfalfa decreases the number of herbicides used to control weeds in alfalfa because glyphosate is the preferred herbicide for GT alfalfa. Adoption of GT alfalfa may increase use of some herbicides used for stand removal. For stand removal adoption of GT alfalfa may result in a shift from glyphosate to other herbicides. Herbicide shifts due to stand removal would be smaller in magnitude than herbicide shifts due to weeds control.

### 3.0 Cultural Farming Practices in Alfalfa

Cultural farming practices include all the methods farmers use to control weeds without the application of herbicides. There are usually multiple benefits of cultural practices beyond weed control. Examples include crop rotation, companion crops, mowing, grazing, burning, tillage, and no-tillage.

#### 3.1 Crop Rotation

For weed, insect, and disease management, it is recommended that alfalfa be used in rotation with other crops (Orloff et al., 1997; Padgitt et al., 2000). Alfalfa is also used in crop rotation because it provides nitrogen to the soil, which decreases fertilizer inputs in other rotations. It can be economically advantageous to include alfalfa in rotations (Mends and Dobbs, 1991).

Perennials and annuals promote and restrict different weeds, so rotating perennials with annuals helps control weeds in general. It is also advisable to rotate alfalfa because mature alfalfa is auto toxic to seedling alfalfa (Xuan et al., 2005). Monsanto recommends that alfalfa can be rotated to grass crops (corn and cereal crops) or broadleaf crops, and that alfalfa should not be rotated with other GT crops (Monsanto, 2008). This limits some options for farmers, as GT corn and GT soybean are both popular rotation crops for alfalfa. Typical rotation crops include wheat, oats, barley, potato (*Solanum tuberosum* L.), sugar beet (*Beta vulgaris* L.), and corn. These are expected to continue as currently practiced because non-glyphosate herbicides are available to manage alfalfa volunteers in each crop. Alfalfa rotation with soybean will remain uncommon because of the lack of nitrogen benefit from alternating between consecutive plantings of legumes. Although the success of rotation with cotton will depend largely on mechanical control of volunteer alfalfa, the number of acres is expected to be low (Rogan and Fitzpatrick, 2004).

The crops that are rotated with alfalfa must have known and available mechanical or herbicidal methods for controlling volunteer alfalfa (Monsanto, 2008). Table J-10 gives an indication of typically recommended crop rotations for alfalfa. These could change as plants and weeds become resistant to glyphosate, or as GT volunteer alfalfa becomes a problem. Crop rotations can help maintain soil fertility, reduce soil erosion, avoid pathogen and pest buildup, adapt to weather changes, avoid allelopathic effects and increase profits (Peel, 1998).

Herbicides that can be used to remove either conventional or GT alfalfa have rotation restrictions. For example, following clopyralid (Curtail® or Stinger®), pea, lentil, potato, and dry bean cannot be planted for 18 months. Picloram (Tordon®) can only be followed by grasses for the year following application. Sunflower, dry bean, and potato should not be planted for several years following picloram (Miller et al., 2006). Dicamba (Banvel®) should not be used prior to soybean and is also limited seasonally in California (Dillehay and Curran, 2006). Because of these restrictions, alfalfa stand removal and rotation schedules should be closely coordinated. Non-glyphosate herbicides are available to manage alfalfa volunteers in wheat, oats, barley, sugar beet, and corn. Therefore rotations from GT alfalfa to those crops should be similar to rotations with non-GT alfalfa (Rogan and Fitzpatrick, 2004). However, if a farmer cultivates another GT crop that would impact crop rotations, and might discourage the use of GT alfalfa as glyphosate could not be used in other crop rotations to control for volunteer alfalfa.

**Table J-10. Recommended Rotations for Pest Reduction (Goodell 2006)**

| <b>Pest</b>                                                                                       | <b>Recommended Rotation</b>                                                                                                                                                                                                  |
|---------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Root knot nematode                                                                                | 1 year rotation with cotton                                                                                                                                                                                                  |
| Stem nematode                                                                                     | 3-4 year rotation with small grains, beans, cotton, corn, sorghum, lettuce, carrots, tomatoes, or forage grasses.*                                                                                                           |
| Diseases:<br>Bacterial wilt<br>Anthracnose<br>Spring blackstem<br>Common leafspot<br>Stagonospora | 3-4 year rotation with small grains, beans, corn, sorghum, forage grasses.*                                                                                                                                                  |
| Winter weeds                                                                                      | A minimum of 1 year (preferably longer) in crops such as small grains, wheat, oats, winter forage grasses that allow the use of selective herbicides that are not registered in alfalfa.                                     |
| Summer weeds                                                                                      | A minimum of 1 year (preferably longer) in crops such as small grains, beans, cotton, corn, sorghum, summer forage grasses that allow the use of selective herbicides that are not registered in alfalfa.                    |
| Dodder                                                                                            | At least 2 years with cotton or other nonhost crops such as small grains, beans, corn, sorghum, or forage grasses. Avoid rotations with crops such as tomatoes, onions, and carrots that also serve as a host for this weed. |
| Nutsedge                                                                                          | Two year rotation with corn or sorghum rotation that includes application of herbicide to control nutsedge.                                                                                                                  |

\* Three to four-year rotations give satisfactory results. A rotation for fewer years will provide minimal suppression.

Adoption of GT alfalfa does affect crop rotations because glyphosate cannot be used for stand removal or volunteer alfalfa control. Therefore other herbicides, which may have rotation restrictions, may need to be used along with tillage to remove GT alfalfa stands. GT alfalfa stands may also last longer than non-GT alfalfa stands (Rogan and Fitzpatrick 2004), therefore adoption of GT alfalfa may influence the number of years that alfalfa is in a rotation. No data was found that quantifies actual differences in herbicide use throughout stand life comparing GT alfalfa with non-GT alfalfa. No data was found that indicates if rotation differences are observed with the adoption of GT alfalfa.

### 3.2 Companion Cropping in Alfalfa

Alfalfa grown for hay is sometimes grown with a companion crop. Companion crops planted with alfalfa are crops that act as weed control and prevent soil erosion, such as oats, spring wheat or peas. They tend to grow much quicker than alfalfa, and out-compete any weeds while alfalfa is becoming established. Once the companion crop begins to compete with the alfalfa for nutrients, water and space, the companion crop can be harvested, and serves as extra profit for the farmer (Smith et al., 1998). At this point, the alfalfa is established enough to compete against any weeds on its own. Oats are the most popular companion crop to alfalfa because they are the least competitive, with alternatives such as peas also in wide use, but exact companion crop habits depend on farmer preference and region (McCordick et al., 2008; Smith et al., 1998). Studies have found that companion cropping in alfalfa can suppress weed growth more than herbicide treatments, but that the crop then competes with the alfalfa, reducing yield (McCordick et al., 2008). As noted in table J-8, companion cropping is more prevalent in the North Central U.S. (Hower et al., 1999).

Companion crops are different from nurse crops in that nurse crops are a specific type of companion crop. Nurse crops do not compete with alfalfa for nutrients, but rather are removed

or killed with herbicide early in development. This can result in both effective weed control and little impact on alfalfa yield (McCordick et al., 2008). Nurse crops can also help reduce wind, water and soil erosion and provide early groundcover like other companion crops (Hall et al., 2004). Other types of companion cropping include using a cover crop, used during dormant seasons to protect the soil, or a barrier crop, used as pest control by serving as a refuge and distraction for pests.

With the development of GT alfalfa, companion cropping options and methods have the opportunity to change. A study by McCordick et al. (2008) looked at the effect of establishment method (companion crops and herbicide interactions) on GT alfalfa establishment. The study found that the highest alfalfa yield came from plots treated with glyphosate, either with or without a companion crop, and that the treatment without herbicide and with a companion crop had the lowest yield, but the system did reduce weed biomass. Also, plots without a companion crop experienced higher dry matter yields than that of plots seeded with a companion crop, indicating that establishing GT alfalfa without a companion crop can maximize production. They also studied the effect of imazamox, another herbicide, on the crops, and found more damage to the alfalfa and lower first harvest yields with use of this herbicide, indicating that the weed control used before the first harvest can significantly impact the crop. Because glyphosate is less damaging to the GT alfalfa, but normal herbicides are still toxic, the results suggest that farmers who grow GT alfalfa can move away from companion cropping and solely use glyphosate for weed control. This would not only reduce potential herbicide damage to the alfalfa, but it could also decrease costs by removing harvesting of the companion crop and increase profits by having more pure alfalfa hay. Exact establishment methods would depend on the goal of the farmer as well as weed presence. Companion crops can decrease weed biomass, but can also decrease yield, and the study concludes that companion crops are not needed with GT alfalfa (McCordick et al., 2008).

### 3.3 Tillage

Tillage fits into the broader context of soil conservation practices. Some soil conservation practices include, chiseling and subsoiling, conservation cover, conservation tillage (no-till, ridge-till, mulch till), contour farming, cover or green manure (legumes), critical area planting (erosion zones), crop residue use, filter strips, grade-stabilization structures, grass and legume in rotation, grassed waterways, strip cropping, and terracing (Caswell et al., 2001).

Tillage practices during cultivation of crops impact the soil and water, and can influence such factors as weed control, crop rotations and yields. Tillage is most often used between crops in order to remove the traces of the previous crop and as weed control in preparation for the next crop. Excessive tillage causes soil erosion. For example, in 100 years half of Iowa's original topsoil eroded (Fawcett and Towery, 2002). Soil degradation has been cited as the most frequent cause of historical cultural decline and civilization collapse (Ragnarsdottir, 2006). Conventional till agriculture fields average one to two orders of magnitude greater soil erosion than natural rates, which is considered unsustainable (Montgomery, 2007). There are multiple types of tillage methods, including conventional tillage, reduced tillage and no tillage. These types of tillage, their uses and their effects are elaborated in table J-11.

Conservation tillage benefits the environment in the following ways (Fawcett and Towery, 2002):

- Reduced soil erosion
- Improved moisture content in soil
- Healthier, more nutrient-enriched soil
- More earthworms and beneficial soil microbes
- Reduced consumption of fuel to operate equipment
- Return of beneficial insects, birds, and other wildlife in and around fields
- Less sediment and chemical runoff entering streams
- Reduced potential for flooding
- Less dust and smoke to pollute the air
- Less carbon dioxide released into the atmosphere

No-till agriculture requires less fossil fuels than conventional agriculture due to decreased use of fertilizers, pesticides, and fuel (Gregory et al., 2005). Both fossil fuel energy consumption and soil compaction (at 15 cm) can be half as much with no-till compared to conventional (Gregory et al., 2005).

Tillage effects cone index, which is a measure of soil strength and soil moisture. Higher cone indexes may lead to reduced crop growth, although cone index effects have not been determined for alfalfa. Preparation of alfalfa seed bed commonly includes deep tillage. Huhnke et al. (1993) measured the effects of different primary tillage practices in alfalfa stand establishment, light disking had the highest cone index and deep primary tillage had the lowest cone index. After the first year cone indexes were not related to primary tillage type. The researchers also concluded that tillage treatment did not significantly affect initial alfalfa population or first year yield. Tillage treatments did have a significant effect on cool-season grass emergence (weeds) within the first month after planting (Huhnke et al., 1993). In another study, forage yield was greater the first year after no-tillage compared to conventional tillage, but there were no differences in yield in the following two years (Malhi et al., 2007). In experimental fields rotated from corn to alfalfa, simulated rainfall and tillage treatments did not strongly affect soil properties, presumably due to a stable soil structure (Karunatilake and van Es, 2002). Forney et al. (1985) found that in experimental sites no-till alfalfa establishment was compromised by factors other than weeds, which is consistent with the concept that reduced-tillage systems generally require more careful management than conventional systems.

No-till farming has grown in popularity since 1996, specifically in crops that since then have had herbicide-tolerant crops introduced. Because the primary purpose of tillage is weed control, farmers can now use and trust herbicide to serve as weed control in its place. Farmers will choose to reduce tillage if they are assured of weed control without disturbing the fields, such as in the case of GT alfalfa where over-the-top glyphosate application is effective (Fawcett and Towery, 2002). Fifty-two percent of GT soybean farmers increased no-till acres after adopting GT soybeans, between 1996 and 2002, while only 21% of non-GT soybean farmers increased no-till acres, indicating a correlation between GT soybeans and decreasing tillage (Fawcett and Towery, 2002). A USDA survey showed that in 1997, 60 percent of GT soybean acres were under conservation tillage while only 40 percent of conventional soybeans were under conservation tillage (Wiebe and Gollehon, 2006). See figure J-9 for the change in tillage

practices from 1990-2002, before and after adoption of GT crops (Fawcett and Towery, 2002). GT crops came on the market in 1996. While use of GT crops encourage reduced tillage, reduced tillage, in turn, encourages increased reliance on herbicide use as weed control. Farmers need methods to manage weeds, and when using GT crops, they will be encouraged to use herbicides (glyphosate) in conjunction with the GT crops. A USDA ERS study from 1994 examined pesticide use based on tillage practices in corn and soybeans, and determined that while herbicide use did increase slightly when tillage was decreased, the biggest difference between tillage methods was the type of herbicides used, not the amount of herbicides total.

**Figure J-9: Conservation tillage adoption in the U.S., 1990-2002**  
(Fawcett and Towery, 2002)

Studies have been performed that look at the impact of GT crops on tillage practices, and also the impact of tillage practices on glyphosate residues in soil and water. The American Soybean Association examined changes in tillage practices once farmers began using GT soybeans, and they found that farmers increasingly used conservation tillage as opposed to conventional tillage (ASA, 2001; Cerdeira and Duke, 2006). When asked why this was the case, 63% of responders stated the GT technology was responsible, as it made cultivation with conservation tillage as effective as conventional tillage. Their reasons included that it reduced weeds, lowered production costs related to fuel and maintenance, decreased the number of labor hours needed for a given field, extended equipment life, and increased yield. The same amount of labor can cover more area elsewhere, leading to increased income. The decreased costs in production might be offset by the increased crop protection costs and the amount of fertilizers needed (Wiebe and Gollehon, 2006).

Tillage can be used in conjunction with GT crops as a form of weed control prior to establishing a stand or for stand removal. If used prior to establishing a stand of alfalfa in order to prepare the land, then this would reduce the amount of herbicide needed for stand establishment (Shukla, 2003).

Sankula (2006) evaluated the impact of biotechnology-derived crops planted in the United States in 2005. A summary of the tillage analysis follows:

- As of 2004 no-till acreage in corn has increased 20 % compared to 1996.
- No till cotton acres increased 371% in 2004 (the most recent year for which information is available) compared to 1996.
- In 2004 about 36% of the total soybean acreage was planted using no-tillage, which represents a 64% increase since 1996.

One study examined the levels of AMPA, a glyphosate residue, in the soil after either low or normal tillage, and found that residues were at higher levels in the low tillage treatment than in the normal tillage treatment, due to increased leaching in the low till treatment (Fomsgaard, 2003). No-till practices can lead to nutrient stratification in the soil because the soil is never mechanically disturbed, and repeated applications of herbicides are made to the surface (Wiebe and Gollehon, 2006). Herbicides that adsorb strongly, such as glyphosate, will be protected from degradation and volatilization, and will not readily leach to ground water. They will only be found in surface water runoff when erosion conditions lead to the loss of surface particles, like in conventional tillage when the soil is highly prone to erosion. Switching to a conservation tillage system, and thus increasing herbicide use, does not increase the likelihood of degradation of water quality through chemical contamination. In general, tillage systems that incorporate low mobility and short persistence herbicides will be better for water-quality standards, with less chance of entering nearby water (Wiebe and Gollehon, 2006). Adopting GT crops would indirectly benefit the environment through the soil conservation practices of conservation tillage, which would increase in popularity (Wiebe and Gollehon, 2006).

Locke et al., (2008) conducted a 6 year conservation tillage field study from 2000 to 2005 at the USDA-ARS Southern Weeds Science Research Unit farm in Stoneville, Mississippi. GT crop rotations were only done from 2003 to 2005. Rotations included continuous GT cotton, continuous non-GT cotton, continuous GT maize, continuous non-GT maize, GT rotation 1 (cotton-maize-cotton), non-GT rotation 1 (cotton-maize-cotton), GT rotation 2 (maize-cotton-maize), and non-GT rotation 2 (maize-cotton-maize). Under continuous GT maize, soils maintained greater soil organic carbon and nitrogen as compared with continuous non-GT maize, but no differences were measured in continuous cotton or in cotton rotated with maize. Soil organisms also showed differences based on fatty acid methyl ester analysis. Locke et al. (2008) concluded that glyphosate use may result in minor effects on soil biological/chemical properties. However, enhanced organic carbon and plant residues in surface soils under conservation practices may buffer potential effects of glyphosate.

Table J-11. Effectiveness of and Restrictions for Herbicides Used for Alfalfa Control

| Herbicide                 | Effect/Efficiency/<br>Resprouting Level                                                                                                                                                                                                                                                                                                 | Tillage                                  | Crop Restrictions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Effect as<br>Volunteer<br>Alfalfa Control<br>(after 2,4-D<br>stand take-out) | Source  |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------|---------|
| 2,4-D                     | Alfalfa was controlled in tilled and non-tilled treatments at 51% and 55%, respectively. Thirty-six days after stand take-out herbicide treatment, 22 days after tillage, and seven days after irrigation, the same treatment provided 100% and 18% control of Roundup Ready alfalfa in tilled and non-tilled treatments, respectively. | Both tilled and non-tilled fields tested | Only the low rate (0.5 L/acre) should be used in the spring. Only field corn or spring cereals can be planted after a spring application, however a 14 day interval between application and planting is required. No specific crop restrictions when applied alone or with glyphosate in the fall. To be safe the following is recommended: If applied alone or with glyphosate before September 1st, then field corn, soybean, spring cereals and canola can be planted in the spring. If applied after September 1st or in the spring, then only field corn can be planted after application.<br>There must be a 60-day harvest interval in new seedlings and 30 days in established alfalfa. | 95%                                                                          | 1, 2, 3 |
| Clopyralid                | When Stinger (clopyralid) was applied to crops at a rate of 3 oz/A, alfalfa was controlled at 84%, 100%, and 96% in no-tillage, plow, and chisel plow conditions, respectively. At a rate of 4 oz/acre, 91%, 100%, and 99%, respectively; and at 6 oz/acre, 93%, 100%, and 100%, respectively                                           | Both tilled and non-tilled fields tested | Rotational restrictions: peas, lentil, potato, and dry bean cannot be planted until 18 months following clopyralid application.<br><br>Application time: in spring before boot stage and/or as a postharvest fall treatment. To control late-emerging Canada thistle, treat preharvest after grass seed is fully developed; apply after most basal leaves emerge but before bud stage.                                                                                                                                                                                                                                                                                                          | 95%                                                                          | 1, 2, 3 |
| Dicamba                   | When Clarity (Dicamba-diglycolamine salt) was applied to crops at a rate of 4 oz/ acre, alfalfa was controlled at 32%, 90%, and 85% with no-tillage, plow, and chisel plow, respectively. When applied at a rate of 8 oz/ acre, effectiveness ranges from 37% (no-tillage), 91% (plow), and 89% (chisel plow).                          | Both tilled and non-tilled fields tested | Can be applied in the fall or spring prior to corn, but should be applied to alfalfa that is actively growing with at least 10 inches of spring growth or 5 inches of post-harvest regrowth. Dicamba should not be used prior to planting soybean or other susceptible crops.<br>It may severely stunt brome grass.<br>Trees, legumes, and broadleaved plants are sensitive to drift and soil residues.                                                                                                                                                                                                                                                                                         | 25%                                                                          | 1, 2, 3 |
| Dicamba and diflufenzopyr | When Distinct (dicamba and diflufenzopyr) was applied to alfalfa at a rate of 4 oz/ acre, 25% of alfalfa was controlled under no-tillage conditions; 88% under plow; and 82% under the chisel plow. When 8 oz/ acre was applied, 34% control                                                                                            | Both tilled and non-tilled               | Acceptable control of alfalfa can better be reached in a competitive cropping system involving small grains.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 75%                                                                          | 3       |

| Herbicide           | Effect/Efficiency/<br>Resprouting Level                                                                                                                                                | Tillage                    | Crop Restrictions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Effect as<br>Volunteer<br>Alfalfa Control<br>(after 2,4-D<br>stand take-out) | Source     |

|                     | was achieved under no-tillage; 90% under plow; and 87% under the chisel plow.                                                                                                          |                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                              |            |
| Glufosinate         | In tilled land after 36 days, glufosinate took out 98% of Roundup Ready alfalfa. In non-tilled land, after 36 days, it controlled 35% control alfalfa.                                 | Both tilled and non-tilled | Canola, corn, and soybean best tolerate glufosinate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 95%                                                                          | 1, 4       |
| Primsulfuron-methyl |                                                                                                                                                                                        |                            | Primsulfuron-methyl recropping restrictions: corn: 0.5 months; sorghum: 8 months; wheat: 3 months; oats: 8 months; rye: 3 months; alfalfa: 8 months; clover: 18 months; soybeans: 8 months.<br>If a field was previously treated with primsulfuron-methyl, sorghum is not a recrop option.                                                                                                                                                                                                                                                                                                                                                                                                                                                | 95%                                                                          | 5          |
| Picloram            | After Tordon (Picloram) application to Roundup Ready alfalfa at a rate of 8 oz/ acre, 98% of alfalfa was controlled under no-tillage, 100% under plow, and 100% under the chisel plow. | Both tilled and non-tilled | Should be applied when the plant is at least 12 inches tall and actively growing. If applied from late June until mid August, there is better residual control the following growing season than either spring or fall treatments. The plants should be mowed in early to mid summer to promote active regrowth prior to a fall treatment. Can be used in pastures, rangeland, and noncropland only. Fields previously treated with Tordon 202C Liquid Herbicide may be seeded to rapeseed, (including canola) mustard, flax, wheat, oats, barley or may be summer fallowed. These crops are tolerant to residues of picloram remaining in the soil. Sunflower, soybean, dry edible bean, and potato are especially susceptible to Tordon |                                                                              | 1, 3, 6, 7 |
| Acetochlor          |                                                                                                                                                                                        |                            | Corn herbicide recropping restrictions: corn: the next year; sorghum: the next year; wheat: 4 months; oats: 2 <sup>nd</sup> year; rye: 2 <sup>nd</sup> year; alfalfa: 2 <sup>nd</sup> year; clover: 2 <sup>nd</sup> year; soybeans: next year. Rotational options: four months for wheat and to next spring (nine months) for soybean, oats, barley, rye, dry beans, sugar beets and potatoes                                                                                                                                                                                                                                                                                                                                             |                                                                              | 5          |

Table J-12. Benefits and Consequences of Various Tillage Systems

| Tillage Types     | Defined                                                                                                                                                                                                                                                                                                                                                                                                                                            | Use                             | Benefits                                                                                                                                                                                                                                                                                                                                                                                                                   | Consequences                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Conventional Till | Full width tillage which disturbs all of the soil surface and is performed prior to and/or during planting. Leaves <b>less than 15 percent residue cover</b> after planting, or less than 500 pounds per acre of small grain residue equivalent throughout the critical wind erosion period. It typically involves plowing or intensive tillage. Weed control is accomplished with herbicides and/or row cultivation.                              | Weed control, field preparation | Highly effective weed control, stand removal, loosens compacted soil                                                                                                                                                                                                                                                                                                                                                       | Causes soil erosion, reduces soil quality and productivity by destroying soil structure, reduces organic matter content and harms beneficial invertebrates such as earthworms, fouls aquatic systems, runoff water contributes to flooding, destroys wildlife food sources, reduces surface crop residues that serve as wildlife cover.                                                                                                                                                                                                       |
| Reduced Till      | Full-width tillage involving one or more tillage trips which disturbs all of the soil surface and is performed prior to and/or during planting. Leaves <b>15 to 30 percent residue cover</b> after planting or 500 to 1,000 pounds per acre of small grain residue equivalent throughout the critical wind erosion period. Weed control is accomplished with crop protection products and/or row cultivation.                                      |                                 |                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Conservation Till | Any tillage and planting system that leaves <b>more than 30 percent residue cover</b> on the soil surface, after planting, to reduce soil erosion by water. Where soil erosion by wind is the primary concern, any system that maintains at least 1,000 pounds per acre of flat, small grain residue equivalent on the surface throughout the critical wind erosion period. No-till, ridge-till, and mulch-till are types of conservation tillage. | Weed control, field preparation | Reduces soil erosion, consumption of fuel to operate equipment, labor cost/hours, improves moisture content in soil, results in healthier, more nutrient-enriched soil, more earthworms and beneficial soil microbes, the return of beneficial insects, birds and other wildlife in and around fields, lessens sediment and chemical runoff entering streams, reduces potential for flooding, decreases amount of dust and | Dependence on herbicides, weed spectrum shifts to perennial weeds, increases herbicide resistant weeds, increases herbicide use, increases danger of crop injury due to reduced tolerance to herbicides or presence of herbicides in the soil affecting crop rotations, inconsistent yields based on climate or soils, complex nutrient management due to higher residue levels and reduced options with regard to method and timing of nutrient applications, nutrient stratification, need to supplement nitrogen in soil for some crops, , |
| Mulch Till        | Full-width tillage involving one or more tillage trips which disturbs all of the soil surface and is done prior to and/or during planting. Tillage tools such as chisels, field cultivators, disks, sweeps, and blades are used. Weed control is accomplished with herbicides and/or mechanical cultivation.                                                                                                                                       |                                 |                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Ridge Till        | Tillage on ridges with sweeps, disk openers, coulters or row cleaners along with nutrient injection. Residue is left on the surface between the ridges. Weed control is accomplished with herbicides and/or mechanical cultivation. Ridges are rebuilt during cultivation.                                                                                                                                                                         |                                 |                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|--------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| No Till              | The soil is left undisturbed from harvest to planting except for planting and nutrient injection. Planting or drilling is accomplished in a narrow seedbed or slots created by coulters, row cleaners, disk openers, in-row chisels or rotary tillers. Weed control is accomplished primarily by herbicides. Cultivation may be used for emergency weed control. Other common terms used to describe no-till include direct seeding, slot planting, zero-till, row-till, and slot-till. |            | smoke to pollute the air, lessens carbon dioxide released into the atmosphere. | high residue cover prevents soil from warming quickly, so plants emerge and grow slowly |

### 3.4 Summary of Findings

Cultural practices such as crop rotation, companion crops, mowing, grazing, burning, tillage, and no-tillage provide multiple benefits to crop production.

Alfalfa is used in crop rotation because it provides nitrogen to the soil, which decreases fertilizer inputs in other rotations. Perennials and annuals promote and restrict different weeds, so rotating perennials with annuals helps control weeds in general.

Adoption of GT alfalfa affects crop rotations because glyphosate cannot be used for stand removal or volunteer alfalfa control. Therefore other herbicides, which may have rotation restrictions, may need to be used along with tillage to remove GT alfalfa stands. GT alfalfa stands may also last longer than non-GT alfalfa stands, therefore adoption of GT alfalfa may influence the number of years that alfalfa is in a rotation. It is recommended that rotations not consist of all GT crops. Because several of the crops that are popular in rotation with alfalfa (corn, soybeans) have GT varieties farmers may have to decide which GT crop provides the most benefit to the rotation plan and overall farm production.

There are several types of companion cropping practices. These include crops that are interseeded with alfalfa and provide protection from wind and harsh weather or outcompete weeds in the stand establishment year, crops that are planted to cover the soil and prevent erosion between growing seasons, and barrier crops along side fields that serve as a refuge for beneficial insects and distract pests. Interseeded companion crops are not likely to be used with GT alfalfa.

Soil conservation practices include, chiseling and subsoiling, conservation cover, conservation tillage (no-till, ridge-till, mulch till), contour farming, cover or green manure (legumes), critical area planting (erosion zones), crop residue use, filter strips, grade-stabilization structures, grass and legume in rotation, grassed waterways, strip cropping, and terracing. GT alfalfa is compatible with all soil conservation practices. GT crops are known to enhance the adoption of conservation tillage.

The cultural practices associated with GT crops and GT alfalfa have a net benefit on soil conservation and quality.

## Appendix J-2.

## Literature Search

### 1.0 Literature Search Strategy

#### 1.1 Purpose

The purpose of this literature search is to locate references about the potential impacts of glyphosate-tolerant alfalfa cultivation practices on water, soil, and air.

#### 1.2 Retrieval criteria

Titles were used to indicate the subject of the paper. If the paper was not in English or indicated a geographic region outside of the U.S., it was not retrieved. Over 90 pages of titles were generated by the searches (see Results below). All titles were reviewed and approximately 50 titles were deemed relevant to provide information on cultivation practices in alfalfa (highlighted in gray in the Results below). The selected titles were searched for online by a professional librarian. Titles that were obtained for free and were cited include the URL in the citation. Titles that were not free access were obtained through online purchase or the use of a copy vendor, who regularly visits National Institutes of Health and National Agricultural Library to obtain references. Not all of the articles were retrieved due to availability. Books that were of marginal interest were not purchased.

## 1.4 Scope of Search

The search focused on any published references between 1990 and the present. A list of titles (below) was screened followed by screening of abstracts for relevant titles. There were no limits on language for titles but only English language publications were retrieved for evaluation.

## 1.5 Key word combinations

Alfalfa OR Medicago AND “organic farm\*”

Alfalfa OR Medicago AND cultivation

Alfalfa OR Medicago AND till\*

Glyphosate AND water AND contamination

Glyphosate AND air AND contamination

Glyphosate AND soil AND contamination

## 1.6 Key Questions

(numbering from original APHIS scope document)

5. What differences are there in weediness traits of conventional alfalfa versus glyphosate-tolerant alfalfa under managed crop production systems as well as in unmanaged ecosystems?

6. What is the occurrence of common and serious weeds found in organic alfalfa systems, in conventional alfalfa systems, and in glyphosate-tolerant alfalfa systems?

What are the current impacts of weeds, herbicide-tolerant weeds, weed management practices, and unmet weed management needs for organic and conventional alfalfa cultivation?  
How may the weed impacts change with the use of glyphosate-tolerant alfalfa?

7. What are the particular management practices for controlling weeds in organic alfalfa systems, in conventional alfalfa systems, and in glyphosate-tolerant alfalfa systems?  
What are the potential changes in crop rotation practices and weed management practices for control of volunteer alfalfa or herbicide-tolerant weeds in rotational crops that may occur with the use of glyphosate-tolerant alfalfa?  
What are the potential effects on alfalfa stand termination and renovation practices that may occur with the use of glyphosate-tolerant alfalfa?  
What is the potential weediness of glyphosate-tolerant alfalfa?

8. What is the potential cumulative impact of glyphosate resistant weeds, especially with the increase in acreage of glyphosate-tolerant crops?  
Are there glyphosate resistant weeds and what is their prevalence in crops and in non-crop ecosystems?  
Will the release of glyphosate-tolerant alfalfa cause an increase in glyphosate resistant weeds in alfalfa and in other crops?  
Which weeds are the most likely to gain glyphosate resistance with the use of glyphosate-tolerant alfalfa?  
What are the alternatives for management of glyphosate-tolerant or other herbicide-tolerant weeds in glyphosate-tolerant alfalfa stands or in subsequent crops?  
What are the potential changes that may occur in glyphosate-tolerant alfalfa as to susceptibility or tolerance to other herbicides?

9. What are current or prospective herbicide-tolerant weed mitigation options, including those addressed by the Environmental Protection Agency-approved label for glyphosate herbicides?

**Appendix K. Changes in the Economics of Alfalfa Farming with Deregulation of Glyphosate-Tolerant Alfalfa**

# **Changes in the Economics of Alfalfa Farming with Deregulation of Glyphosate-Tolerant Alfalfa**

## **Executive Summary**

This report analyses the potential impact on the economics of alfalfa farming due to the introduction of glyphosate-tolerant (GT) alfalfa into the market. It does so by reviewing the existing literature on alfalfa costs and returns, as well as on the potential impacts of GT alfalfa adoption. Based on this literature, scenarios of returns with GT alfalfa are constructed and described, where possible. Additional considerations are made regarding the potential long-term economic consequences of increased glyphosate resistance of weeds.

The report finds that alfalfa forage farmers aiming at maximizing returns during the time horizon of an alfalfa life stand would likely benefit financially from the adoption of GT alfalfa due to potential improvements in forage quality with reduced herbicide costs. The impact of GT alfalfa adoption for seed production is not as clear, given its dependence on conditions established by breeder company – producer contracts.

The increased returns expected for GT alfalfa farming in the short run may or may not persist in the long run, depending on market considerations (including technological fees), limitations to crop rotation imposed by the adoption of GT alfalfa, and cost impacts of any possible increased weed resistance over time.

A final analysis ranking counties based on the likely benefits of GT alfalfa adoption is presented at the end of this report and should be interpreted within the limited scope of this report.

## 1.0 Introduction

### 1.1 Objective, Scope, and Organization of Report

This report analyses the potential impact on the economics of alfalfa farming of the introduction of glyphosate-tolerant (GT) alfalfa into the market. By “economics of alfalfa” farming we refer to the costs of production and yields and their implications for farm income. Our analysis is restricted to looking at individual farms: we do not aggregate farmers to draw inferences on supply. This analysis – as well as demand considerations – is left for the remaining socioeconomic Technical Reports. In particular, the Technical Report *Economic and Social Impacts to Organic Farmers of Deregulation of Roundup Ready Alfalfa* (appendix S) will also include the impacts on farmers of conventional alfalfa.

Below we explain the methodology – assumptions, scenarios and limitations – upon which this analysis is based. Section 2 focuses on the production of alfalfa hay and section 3 on the production of alfalfa seeds. In both of these sections, we assume no glyphosate resistance in weeds. This assumption is relaxed in section 4 where we consider the impacts of increased glyphosate resistance of weeds on both hay and seed production, as well as on crops with which alfalfa is rotated on the farm.

### 1.2 Methodology

Alfalfa farming for forage and for seed are analyzed separately, the former in section 2, the latter in section 3. These are the two main – and quite distinct – cropping systems for alfalfa.

In section 2, we start with a brief description of alfalfa farming for forage, its cost factors and its value for the farmer. We then review the existing cost studies of alfalfa farming and identify the main factors affecting economic returns for alfalfa farmers. We then review the literature on the possible differences between conventional alfalfa farming and GT alfalfa farming, regarding those cost and return factors. The same methodology is adopted in section 3 regarding alfalfa farming for seed.

In section 2 we go a step further and build scenarios for GT alfalfa costs using some of the cost studies identified for conventional alfalfa. As alfalfa farming conditions vary considerably throughout the United States, these scenarios assume all conditions of the base conventional cost studies remain the same, except a few major changes previously identified as likely to occur in GT farming. The results are offered as an illustration of potential differences in costs and returns for the farmer under specific situations. We did not build similar scenarios in section 3. To do so would require investigation in greater depths into breeder company and seed grower agreements.

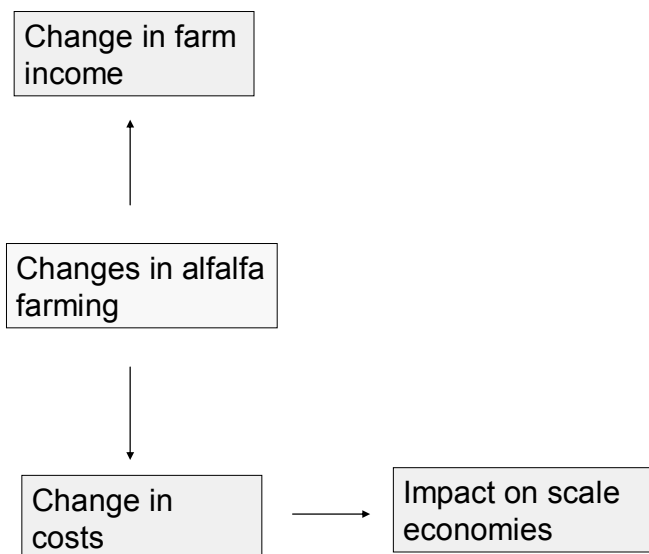

Sections 2 and 3 look at economic impacts to farmers when they plan with the time horizon of the life of an alfalfa stand, and assume no weed resistance occurs within this time horizon. Section 4 raises a few considerations regarding economic impacts beyond this time horizon and regarding weed resistance to glyphosate and its potential growth on alfalfa farms, whether in

alfalfa fields or in crops rotated with alfalfa. These considerations are based on the existing literature and on the analyses done in sections 2 and 3.

In appendix K-3 of this technical report, we present county level analysis identifying those counties that would most likely benefit from GT alfalfa deregulation, based solely on the short-term cost-return considerations made in section 2, and not incorporating considerations that will be dealt with in later Technical Reports (e.g. demand considerations, beyond the scope of the present report). It transposes, to the extent possible, the analysis done in this report to the county level.

### 1.2.1 Assumptions

Cause-effect relationships assumed in our analysis of the potential socioeconomic impacts of GT alfalfa on alfalfa farming stem from two potential sources of physical impacts. The first is the availability of a new variety of alfalfa with its own traits and implications for costs and farm income. The figure below illustrates the impact of the availability of this new variety, showing also potential implications for scale economies.

**Figure K-1: Changes in alfalfa farming**

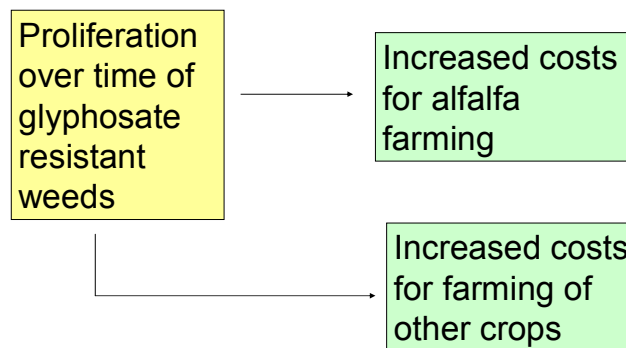

Change in alfalfa farming may imply more or less use of various inputs and higher or lower yields of alfalfa hay and seed. This leads to changes in the costs of producing alfalfa and potential impacts on economies of scale. It also results in changes in farm income.

Changes in costs of producing alfalfa could also have implications for the use of labor. We have not included analysis of this here for two reasons: a) the literature and cost studies we found

largely omit information on the use of farmers own or family labor; b) we found little to no reference on changes in the use of own or hired labor in the adoption of GT alfalfa.

For this analysis we assume no growth in glyphosate resistant weeds has yet followed from the increased use of glyphosate.

The second source of change in alfalfa farming is the growth in glyphosate-tolerant weeds that is expected from the increased use of glyphosate over time. This has implications not only for alfalfa farming but also for farming of other crops rotated with alfalfa, so we include the analysis of impacts on other crops as well.

**Figure K-2: Proliferation of glyphosate resistant weeds**

### *1.2.2 Data and Information Sources*

Most of the information on alfalfa production comes from documents published by university cooperative extension services. Some of these documents are peer-reviewed before publishing and others were presented at specialized conferences. Other sources of information and data include academic journals, producer associations, specialized internet portals and magazines and government official data sources.

## 2.0 Changes in Alfalfa Farming for Forage

### 2.1 Conventional Alfalfa Farming For Forage

Harvested acreage of alfalfa hay (dry) was in 2007 almost 21.7 million acres generating some 72.6 million tons of hay at an average yield of 3.35 tons per acre (USDA NASS, 2008)<sup>39</sup>. Statistics for acreage of alfalfa used as haylage (alfalfa baled at a higher moisture content than dry hay) are not available for all states except in the Agricultural Census, but based on the 2007 census and more recent USDA NASS data available for 18 states, haylage acreage should account for an additional 10%-15% in alfalfa acreage grown for forage. It is the fourth crop in acreage in the United States (USDA NASS, 2008; 2009).

Alfalfa is grown for forage in almost all of the U.S. states and farming conditions vary considerably depending on climate, rainfall, soil fertility, weed and disease prevalence, whether it is seeded in fall or in spring, for dairy or other use, among other factors. In a study conducted between 1988 and 2002 on pesticide use in alfalfa, Hower et al (1999) differentiate between four distinct regions of alfalfa farming: North Central, West, Northeast and South. The North Central region presented the highest acreage of alfalfa followed by the West. Together these two regions had 90% of the alfalfa acreage in the country. The West, however, presented the highest yields, relatively high prices, most seeding done in fall and relatively high rates of insecticide and herbicide use, while the North Central region presented the lowest yields, lowest prices, most seeding done in spring and the lowest rates of insecticide and herbicide use. According to this report, only 8.1% of alfalfa hay acreage in the North Central region was treated with herbicides, while in the West 50% of acreage was treated with herbicides..

Rogan and Fitzpatrick (2004) follow the regionalization adopted by the USDA-Plant Variety Protection Office and the National Alfalfa and Miscellaneous Legume Variety Review Board that divides alfalfa production in seven regions: Southeast, East Central, North Central, Great Planes, South West, Winterhardy Intermountain and Moderately Winterhardy Intermountain. More than half of the alfalfa forage acreage is grown in the North Central region. This region tends to use winterhardy varieties, harvest 2-5 times a year, has yields lower than national average and often uses companion crops to control weeds during establishment of alfalfa. A similar characterization is done of the East Central region. In contrast, in the Southwest region some non-dormant varieties are used allowing for 8-11 harvests a year Rogan and Fitzpatrick (2005). In some locations in California, yields can reach 14 tons/ acre (Klonsky et al, 2007)

Klonsky et al (2007) characterize alfalfa as being a relatively low risk crop, valued by farmers for its cash flow properties, often harvested many times a year, while waiting for the harvest of other crops. It is also valued as a rotational crop since it has beneficial properties on the soil (Putnam et al, 2007).

Klonsky et al. (2007) summarize average costs from various cost studies done for alfalfa by the University of California-Davis, in collaboration with the UC Cooperative Extension, for several

---

<sup>39</sup> This includes alfalfa hay mixtures.

parts of California. Throughout the state, major sources of variation in costs are irrigation and land values. Harvesting costs also vary considerably depending on the number of harvests per year allowed by the local climate. Putnam et al (2007) consider the limitation of water supply as being the main determinant factor of the future of alfalfa production in California.

### *2.1.1 Cost Studies*

There are several cost studies done by university cooperative extension services available both for production of alfalfa hay and alfalfa haylage.

The University of Nevada conducted multiple cost studies for alfalfa hay production. A 1998 study in Humboldt County (Kettle et al., 1999b) found costs associated with 500 acres of alfalfa hay using center pivot irrigation. The study found irrigation power to be the highest cost component (22.3%) of total variable costs of production. Chemical weed control accounted for 10.7 percent of total operating costs. These figures differed only slightly from a 1996 cost study for costs associated with 960 acres of alfalfa (Myer et al., 1997). The study also found irrigation to be the highest cost component (26.8%), and found slightly lower costs associated with chemical weed control (9.2%).

A 2006 study conducted in Pershing County, Nevada (Brezeale et al., 2006) calculated costs for alfalfa hay stand establishment and production for farms with 750 acres of alfalfa cultivation. For stand establishment, the study results show no component accounting for a significant amount of the operating costs; fuel and lube, fertilizer, and maintenance together accounted for 42 percent of total operating costs. Herbicide use during stand establishment comprised 4.8 percent of operating costs. For hay production, the study shows maintenance (19.6%), fuel and lube (18.9%), hired labor (17.9%), and operator labor (16.4%) accounting for more than 70 percent of operating costs. Herbicide use accounts for 7.5% of operating costs during production.

A 2003 Ohio State University Extension alfalfa haylage production budget (The Ohio State University Extension, 2003) estimated costs for different yields of alfalfa haylage for a four year stand. The study found chemical use (Bathryoid, Poast, and Butyrac) to be the highest cost component of operating costs. The proportion of the budget in chemical use decreased with yield; for a yield of 8 tons/ acre chemical use accounted for 21.9 percent of operating costs, for a yield of 13 tons/ acre chemical use accounted for 18.1 percent of operating costs. A 2007 Virginia Cooperative Extension alfalfa haylage cost study (Virginia Cooperative Extension, 2007) found fertilizer use to be the highest operating cost component (41.4%) of operating costs for a 9 ton yield. Herbicide use accounted for 14.6 percent of total operating costs.

We detail two other cost studies below, one for California, the other for Wisconsin, in an attempt to better illustrate some of the varying local conditions in alfalfa production.

The most recent cost study we found comes from the University of California Cooperative Extension with sample costs for establishing and producing conventional alfalfa in a 50 acre extension in the San Joaquin Valley (Frate et al., 2008). Table K-1 below summarizes the costs for establishing alfalfa. Total cultural (land preparation and plant growing) costs include land preparation, fertilizers, planting and irrigation. Cash overhead costs are the costs for insurance,

office expenses and taxes. Non-cash costs are capital recovery costs for land, the irrigation system and the equipment. The seeding rate is assumed to be 30 lbs/acre. We show the line items for seeds and herbicides, more details are found in the publication.

**Table K-1. Establishment Costs, \$/ acre**

|                                       |        |
|---------------------------------------|--------|
| Seeds                                 | 90.00  |
| Herbicides                            | 32.00  |
| Other                                 | 314.00 |
| TOTAL CULTURAL COSTS                  | 436.00 |
| Interest on operating capital @ 6.75% | 10.00  |
| TOTAL OPERATING COSTS/ ACRE           | 446.00 |
| Cash overhead costs                   | 85.00  |
| CASH COSTS/ACRE                       | 531.00 |
| Non-cash costs/ acre                  | 294.00 |
| TOTAL COSTS/ACRE                      | 825.00 |

Source: Frate et al., 2008

Table K-2 shows how establishment costs per acre vary with changes in seed and herbicide costs. The first column shows the increase assumed for seed costs or for herbicide costs. The second and third columns show the impact on establishment costs when it is seed costs that increase 10%, 20%, 30% or 40%, and the fourth and fifth columns show the impact on establishment costs when it is herbicide costs that face a similar increase.

Table K-2 shows that seed costs have a greater weight than herbicide costs in determining total establishment costs, under the conditions of the US Cooperative Extension Study.

**Table K-2. Sensitivity of Establishment Costs to Changes in Seed and Herbicide Costs**

| Percent increase in input costs | Establishment costs when seed costs increase |          | Establishment costs when herbicide costs increase |          |
|---------------------------------|----------------------------------------------|----------|---------------------------------------------------|----------|
|                                 | \$                                           | % change | \$                                                | % change |
| 0                               | 825.0                                        |          | 825.0                                             |          |
| 10%                             | 834.0                                        | 1.09%    | 828.2                                             | 0.39%    |
| 20%                             | 843.0                                        | 2.18%    | 831.4                                             | 0.78%    |
| 30%                             | 852.0                                        | 3.27%    | 834.6                                             | 1.16%    |
| 40%                             | 861.0                                        | 4.36%    | 837.8                                             | 1.55%    |

Source: based on previous table

Table K-3 incorporates establishment costs into total costs of producing alfalfa by assuming annual cost recovery of cash establishment costs spread over a 4 year life of stand. Cultural costs now include herbicides, insecticides, fertilization and irrigation. Income from alfalfa hay sales is also incorporated and seven harvests are assumed in a year. The UC Cooperative Extension study assumed a yield of 8 tons/ acre, average of yields between 5 and 11 tons/ acre obtained under these conditions in the San Joaquin Valley. The table shows positive returns over operating costs, but negative returns when overhead and capital costs are included.

**Table K-3. Total Production Costs and Returns, \$/ acre**

|                                             |          |
|---------------------------------------------|----------|
| Sales (8 tons/acre at \$185/ton of premium) | 1,480    |
| Herbicides                                  | 71.00    |
| Other cultural costs                        | 294.00   |
| Harvest costs (7x)                          | 310.00   |
| Interest on operating capital @ 6.75%       | 10.00    |
| Total operating costs/ acre                 | 685.00   |
| Return over operating costs                 | 795.00   |
| Cash overhead costs                         | 165.00   |
| Annual cost recovery: alfalfa establishment | 147.00   |
| Annual cost recovery: other                 | 549.00   |
| Total costs/acre                            | 1,546.00 |
| Return over total costs                     | -66.00   |

Source: Frate et al., 2008

Table K-4 shows how returns per acre vary with changes in seed and herbicide costs, as well as changes in yields or hay prices. As in table K-2, the first column represents the percent increase assumed if a given factor is affecting returns. In this case: seed costs, herbicide costs or the yield multiplied by the price of alfalfa hay. The remaining columns show the impact on returns when the percent increase assumed is applied to seed costs, herbicide costs, yields or the price of alfalfa hay.

The table shows that the influence of herbicide costs now surpasses that of seeds on total costs, since now herbicides are also used during production. The table also shows, however, that under the conditions of the US Cooperative Extension Study, yields and hay prices are far more important than seed and herbicide costs in determining returns.

**Table K-4. Sensitivity of Returns to Changes in Costs, Yields and Hay Prices**

| Percent increase | Seed costs |          | Herbicide costs |          | Yields or Hay prices |          |
|------------------|------------|----------|-----------------|----------|----------------------|----------|
|                  | \$         | % change | \$              | % change | \$                   | % change |
| 0%               | -66        |          | -66             |          | -66                  |          |
| 10%              | -68.49     | 3.77%    | -73.99          | 12.11%   | 82                   | 224.24%  |
| 20%              | -70.49     | 6.80%    | -81.97          | 24.20%   | 230                  | 448.48%  |
| 30%              | -73.48     | 11.33%   | -89.96          | 36.30%   | 378                  | 672.73%  |
| 40%              | -75.97     | 15.11%   | -97.94          | 48.39%   | 526                  | 896.97%  |

Source: based on previous table

The Integrated Pest and Crop Management Portal of the University of Wisconsin Plant Sciences outreach programs posts a “Roundup Ready Alfalfa Calculator” elaborated by Dan Undersander (<http://ipcm.wisc.edu/WCMNews/tabid/53/EntryID/208/Default.aspx>). Table K-5 shows the results of this calculator for conventional hay, as presented on the website. We include the results for Roundup Ready alfalfa further below. Values are those that the portal feels “are accurate estimates of the costs, use patterns, and yield throughout Wisconsin.” However the numbers are not supposed to be representative of every farmer, and the calculator is offered so that each farmer can plug in their numbers and see the results.

**Table K-5. Establishment and Production Cost of Conventional Alfalfa, units/acre**

|                                                  |          |
|--------------------------------------------------|----------|
| Seed cost/ 50 lb bag (\$)                        | \$200.00 |
| Pounds of seed per acre                          | 12       |
| Technology fee/bag (\$/bag)                      | \$0.00   |
| Yield in seeding year (t/a DM)                   | 3.50     |
| Herbicide cost (\$/acre/application)             | \$20.00  |
| Herbicide application cost (\$/acre)             | \$10.00  |
| Number of herbicide applications                 | 1        |
| Value of ease of roundup use (\$/acre)           | \$0.00   |
| Yield depression from pursuit/raptor (t/a DM)    | 0.30     |
| Expected stand life (yrs including seeding year) | 3        |
| Value of hay (per ton DM)                        | \$100.00 |
| Fixed costs per acre per year                    | \$180.00 |
| Harvesting costs per acre per harvest            | \$35.00  |
| Number of harvests                               | 2        |
| Seeding Year Production Costs/Results            |          |
| Seed cost (prorated + tech fee) per acre*        | \$16.00  |
| Total seed and herbicide cost per ton of hay     | \$14.38  |
| Total cost per ton of hay seeding year           | \$85.80  |
| Profit per acre - seeding year                   | \$49.69  |

Source: Integrated Pest Crop Management, University of Wisconsin

The University of Wisconsin portal also presents some sensitivity analysis. We extend their analysis to include herbicide costs and the price of alfalfa hay, since these variables may potentially differ between conventional and GT alfalfa, as argued in section 2.2 below. We use the numbers for the seeding year above to have an idea of the changes in profit for percent changes in seed costs, herbicide costs and the price of hay. Table K-6 shows the results for a conventional alfalfa hay field. The first column represents the percent increase assumed in a given factor affecting returns. The remaining columns show the impact on per acre profit when the percent increase assumed is applied to seed costs, herbicide costs or the price of alfalfa hay.

**Table K-6. Sensitivity of Profit per Acre to Costs and Prices**

| % increase | seed costs | herbicide costs | price of alfalfa hay |
|------------|------------|-----------------|----------------------|
| 0          | 49.69      | 49.69           | 49.69                |
| 10         | 47.94      | 47.50           | 84.69                |
| 20         | 46.19      | 45.31           | 119.69               |
| 30         | 44.44      | 43.13           | 154.69               |
| 40         | 42.69      | 40.94           | 189.69               |

Source: Elaborated from numbers in table above.

While a 40% increase in seed costs and herbicide costs have a less than proportional impact on profit, a 40% increase in alfalfa hay prices will more than triple the profit per acre. What this means is that reductions in the costs of herbicides are less important in the farmer's choice of adopting GT alfalfa or conventional alfalfa for hay than the possibility of obtaining higher quality alfalfa hay.

As percentage changes in yield also seem to have a high impact on returns, it could be argued that farmers of conventional alfalfa face a trade off between pursuing higher yields of alfalfa of lower quality, by harvesting a shared alfalfa-weed mix, or pursuing higher prices of alfalfa with lesser weed content. In fact, it seems that differences in prices between high quality and low quality alfalfa hay are highest in times of average low prices (Holin, 2008). In those seasons it may be worth favoring quality over yield. In years when average prices are high, favoring yields may pay off.

### *2.1.2 Scale Economies*

Some insight on the potential link between alfalfa varieties and economies of scale is provided by the exercise below in which we compare costs for a 300 acre alfalfa hay farm with those of a 50 acre alfalfa hay farm, under similar circumstances, as made possible by two studies from the University of California Cooperative Extension (Frate et al., 2008; Mueller et al. 2008).

The University of California Cooperative Extension Service produced a similar study to that of the 50 acre farm in San Joaquin Valley for a 300 acre farm in the same region (Mueller et al., 2008). Most of the assumptions are the same such as seeding rate and price received per ton of premium hay; other aspects were adapted to production on a larger scale. These include:

- yields are assumed to be 9 tons/ acre, where the additional ton (compared to the 8 tons/ acre of the 50 acre farm) is the equivalent in haylage of 3.03 green tons with 30% dry matter. This additional ton is sold at \$46.67 (roughly the difference between hay and harvest costs, divided by three);
- land preparation costs are lower per acre, making establishment costs per acre lower in the 300 acre farm than in the 50 acre farm;
- insurance and property taxes are higher for the entire farm, but lower per acre.
- the life of stands is assumed to be three years instead of four.

Table K-7 below summarizes the total costs and returns for establishing and producing alfalfa on a 300 acre farm in the San Joaquin Valley, as compared to a 50 acre farm in the same region.

**Table K-7. Total Production Costs and Returns, \$/ acre**

|                                             | <b>300 acre farm</b> | <b>50 acre farm</b> |
|---------------------------------------------|----------------------|---------------------|
| <i>Sales</i>                                | <i>1620a</i>         | <i>1480</i>         |

| <i>Total operating costs/ acre</i>          | <i>708.00</i>        | <i>685.00</i>       |
| <b>Return over operating costs</b>          | <b>912.00</b>        | <b>795.00</b>       |
| Cash overhead costs                         | 122.00c              | 165.00              |
| Annual cost recovery: alfalfa establishment | 173.00d              | 147.00              |
| Annual cost recovery: other                 | 359.00e              | 549.00              |
| <i>Total costs/acre</i>                     | <i>1,362.00</i>      | <i>1,546.00</i>     |
| <b>Return over total costs</b>              | <b>258.00</b>        | <b>-66.00</b>       |

Source: Mueller et al., 2008. a. Eight tons hay, one ton haylage; b. Seven hay harvests, two haylage; c. Lower liability insurance and property taxes per acre; d. Establishment costs/ acre are actually lower for 300 acre farm thanks to reduced land preparation costs, but divided over shorter three year life of stand; e. Lower land cost recovery.

Even with a shorter life of stand and higher operating costs per acre, returns per acre are higher for the 300 acre farm due to: a) lower overhead and capital recovery costs, including lower land preparation costs in establishing alfalfa stands (economies of scale on the size of land); and b) increased yields. In the 50 acre and 300 acre studies compared above, the higher per acre land preparation costs for the 50 acre farm seem to originate from a greater reliance of custom operators.

What this analysis suggests is that any alfalfa variety that is more demanding of land preparation will likely be more attractive to larger farmers, while alfalfa varieties that allow for less expense in land preparation, may be more accessible to smaller farmers than other varieties.

## 2.2 GT Alfalfa Hay Farming

Evidence of farming distinctions between GT alfalfa and conventional alfalfa come mostly from field trials and from those farmers that planted alfalfa during the window in which it was deregulated, between June of 2005 and March of 2007. During this period over 300,000 acres of GT alfalfa are estimated to have been planted (Putnam, 2007). Much of this latter type of evidence is anecdotal, in that it is based on the observation of one or a few GT alfalfa fields.

Canevari (2007) presents a small (non-random) survey with 24 growers in addition to a few consultants, seed and marketing dealers, and university faculty where the main aspect of GT alfalfa observed was the control of weeds with glyphosate, generally to the satisfaction of the users. According to this paper, GT alfalfa would reduce the costs of herbicides while improving the quality of alfalfa hay (lesser weed content). Miller et al (2006) refers to field trials done at the University of Wyoming and University of Nebraska and suggest the main features of GT alfalfa are its “ease of use, flexibility, and broad spectrum weed control.”

Individual farmers that had experimented with GT alfalfa after initial deregulation and that sent comments to APHIS’ Notice of Intent to prepare an Environmental Impact Statement provide

additional reports, including that of possible increase in yields (due to lesser stunting caused by use of other herbicides) and reduction in herbicide costs.

Reduced seeding rates or increased life of stands would have relevant impacts on costs because establishment costs would be reduced (per year of production). Van Deynze et al. (2004) suggested GT alfalfa could potentially increase the life of alfalfa stands but we have not found studies verifying this.

Given the economic relevance for alfalfa farming of yields and alfalfa hay quality evidenced in the cost studies reviewed above, we reviewed the literature for evidence of differences in those particular traits between GT alfalfa and non- GT alfalfa.

### 2.2.1 Differences in Yield

Alfalfa hay yield is influenced by a wide range of factors, including seed variety, proper planting and establishment, climate, soil and moisture conditions, and weed and insect control (Dixon et al. 2005). Hundreds of alfalfa varieties have been developed for use in North America. These varieties are adapted to the various major alfalfa production zones, and contain genes selected for high yield and resistance to diseases, insects, and nematodes (Van Deynze et al. 2004).

The focus here is on evaluating any systematic differences in yield between GT and conventional alfalfa varieties, holding constant the other factors that may influence yield. Rigorous assessment of the yields of different alfalfa varieties under actual farming conditions is generally not available. Instead, forage agronomists usually evaluate different varieties in the context of controlled variety trials at agricultural experiment stations (Mueller 2008).

Comparative yield data from a number of variety trials across the United States are given in Table K-8. These results were selected for illustrative purposes, and do not necessarily represent the yield outcomes that would result from individual cultivar comparisons, or other locations and growing seasons.

**Table K-8. Comparative Variety Trial Yield Results**

| Variety Trial Location and Date                | Average Annual Yield, All GT Alfalfa Varieties (Tons/Acre) | Average Annual Yield, All Varieties (Tons/Acre) |
|------------------------------------------------|------------------------------------------------------------|-------------------------------------------------|
| Illinois (Freeport), 2007 <sup>1</sup>         | 6.10                                                       | 6.17                                            |
| Iowa (Ames), 2007 <sup>2</sup>                 | 4.61                                                       | 4.64                                            |
| Kansas (Thomas Co.), 2007 <sup>3</sup>         | 8.22                                                       | 8.41                                            |
| Nebraska (Havelock), 2006 <sup>4</sup>         | 5.04                                                       | 5.12                                            |
| New York (Cobleskill), 2006 <sup>5</sup>       | 2.6                                                        | 2.9                                             |
| South Dakota (Brookings Co), 2006 <sup>6</sup> | 3.81                                                       | 3.86                                            |
| Wisconsin (Lancaster), 2006 <sup>7</sup>       | 4.77                                                       | 4.07                                            |

7. Source: <http://www.uwex.edu/CES/crops/RRAlfalfa07.htm>

As revealed in table K-8 above, variety trial results do not indicate any systematic hay yield advantage or disadvantage for GT alfalfa hay cultivars. Dr. Daniel Putnam, a leading alfalfa

research agronomist at UC-Davis, has been conducting variety trial testing of GT and other alfalfa cultivars throughout California. Putnam (2008) notes that in general, the yield performance of GT alfalfa cultivars (as a group) are no different than what could be expected from similar conventional lines of equal fall dormancy characteristics. Moreover, he notes that there are differences between conventional varieties that are due to fall dormancy, and due to the superiority of individual cultivars within a dormancy group, but the range of variation observed in conventional cultivars is similar to the range of variation observed in GT cultivars (Putnam 2008).

Looking beyond comparative yield analysis under controlled variety trial conditions, a key factor influencing alfalfa hay yield under actual farming conditions is weed control during stand establishment (Dillehay and Curran 2006). Weed management in alfalfa is critical during stand establishment to ensure a successful plant population. Alfalfa seedlings establish slowly and are very sensitive to competition for limited resources (Dillehay and Curran 2006). Weed infestation during the establishment of an alfalfa hay crop increases weed seed reserves and decreases seedling vigor in an alfalfa stand (Van Deynze et al. 2004). Thus controlling weeds during the establishment year reduces stress on alfalfa, increases seedling weight and leaf numbers, and ultimately increases yields the following year (Stout et al. 1992). Van Deynze et al. (2004) note that weed control has an even more important impact on the forage quality of alfalfa hay, an issue that will be addressed in the next section.

One of the major incentives to plant GT alfalfa is to control weeds during establishment (Van Deynze et al. 2004). A weed management system in which glyphosate is applied at the proper alfalfa growth stage during stand establishment provides more than 95 percent control of nearly all weeds (Van Deynze et al. 2004; Dillehay and Curran 2006). By way of comparison, Dillehay and Curran (2006) found somewhat weaker weed control using other herbicides such as Buctril, Butyrac, Pursuit, and Raptor. Application of glyphosate at the seedling stage will also normally cause a three to seven percent seedling mortality rate, due to the normal occurrence of a small number of GT alfalfa seeds lacking the gene for glyphosate tolerance. This is not considered a problem in actual practice, however, as it is common for more than 40 percent of seeds sown to fail to establish prior to the first or second cutting in a normal process of self thinning (Van Deynze et al. 2004).

The application of herbicides may also cause crop injury and seedling mortality. Van Deynze et al. (2004) and Dillehay and Curran (2006) found that glyphosate applications caused little to no alfalfa injuries that were evident by the time of the first cutting. By way of comparison, Van Deynze et al. (2004) report that Raptor and Pursuit plus Buctril tank mix treatments resulted in higher injury ratings, usually of less than 20 percent. Rankin (undated) assumes a 6.67 percent conventional alfalfa hay yield reduction for crop injury based on conventional weed management systems. Rankin cites evidence from Wisconsin of no significant difference in total season yield between GT alfalfa with a glyphosate weed management system and conventional alfalfa hay production, but notes virtually the entire yield from the GT alfalfa system was alfalfa, while at least some of the yield from the conventional system was weeds.

Taken together, the evidence suggests that there is no intrinsic yield advantage in GT alfalfa cultivars over conventional cultivars. The evidence suggests a potential yield advantage for GT alfalfa using the glyphosate weed management system, particularly during stand establishment.

### *2.2.2 Differences in Quality*

The forage quality of alfalfa is based on a large number of factors that are ultimately linked to its utility as an animal feed (Baker and Ball 1998). Federal quality guidelines currently use percentage of crude protein and acid detergent fiber, relative feed value, and an evaluation of color, molds or weeds present (McWilliams et al. 2005). Alfalfa is then placed in five quality categories: supreme, premium, good, fair and low. Some states have adopted additional quality grading regulations. Dairy cattle and horses both tend to have high forage quality requirements (Van Deynze et al. 2004). Most weeds are lower in forage quality or palatability than alfalfa, and forage with high weed content can adversely affect milk production as well as animal growth and health (Van Deynze et al. 2004).

As noted in the preceding subsection, Van Deynze et al. (2004), Dillehay and Curran (2006), and Rankin (undated) all report better weed control in GT alfalfa using the glyphosate weed management system. Glyphosate controls a broader spectrum of weeds and is more efficacious than most currently available herbicides and herbicide combinations during the critical stand establishment stage of alfalfa production (Van Deynze et al. 2004; Dillehay and Curran 2006), and induces less crop injury in established stands (Van Deynze et al. 2004).

Conventional alfalfa hay varies in terms of weed content, and so it is difficult to make direct comparisons between GT and conventional alfalfa hay from a weed content standpoint. Quality grading assigns penalties based on weed and other contaminant content. Cummings et al. (2004) utilized an alfalfa hay pricing system in which each 15 percentage point increase in weed content above a benchmark 5 percent level resulted in a 10 percent reduction in the price of the alfalfa hay. Van Deynze et al. (2004) note that pure alfalfa hay is usually worth 20 to 50 percent more than weedy hay. Putnam (2008) argues that while the relative weed-free nature of GT alfalfa tends to give it a quality edge over conventional alfalfa, one cannot systematically attribute higher quality to GT alfalfa over conventional alfalfa, since sometimes conventional weed control systems can be quite effective.

The limited evidence presented here suggests that while there is the potential for higher quality forage from GT alfalfa, one cannot systematically assume higher quality attributable to GT alfalfa over conventionally produced alfalfa.

### *2.2.3 Scenarios*

Based on the review above, we use the cost studies previously mentioned and ask what would happen under the same assumptions but with the use of GT seed, glyphosate, and under various scenarios of alfalfa hay quality. No differences in yield are assumed between GT alfalfa and non-GT alfalfa, and no additional differences in management systems are assumed.

These scenarios should not be interpreted as likely differentials in costs and returns between conventional and non-GT alfalfa in any particular setting, since the differences in management

systems between the two varieties are likely to involve other factors not taken into consideration in the scenarios (such as the time spent by farmers with weed control) and the impact of the deregulation of GT alfalfa on the prices paid for alfalfa of various qualities is ignored (this will be analyzed in a future Technical Report, since it is not part of the scope of the present report). However, given the importance of differences in seed, herbicide use and potentially in alfalfa forage quality between conventional and GT alfalfa, we feel these scenarios provide a useful illustration of what the potential cost and return implications may be of adoption of GT alfalfa for forage.

A note on removal costs: removal of GT alfalfa stands can be done both through mechanical and chemical methods and one source describes plowing as possibly the most common method for alfalfa stand removal (Orloff and Putam, No Year). When herbicides are used for removal, glyphosate seems to be the most common (Canevari 2004). However, glyphosate cannot be used to remove GT alfalfa stands.

Differences in removal costs of alfalfa stands are not considered in this exercise, because they are also not included in the cost studies used as comparison. Glyphosate as an herbicide in the removal of alfalfa stands apparently can be substituted by other herbicides. One study done by Mark Renz at the University of Wisconsin with various herbicides found that “all herbicides were effective at limiting resprouting of alfalfa at the appropriate rate and timing” (Renz, 2007). Canevari et al (2004) suggest a combination of 2,4-D and Banvel (dicamba) was particularly effective. Miller et al (2006) suggest various options while alerting to the restrictions of these herbicides for future crop rotation.

Based on the existing literature, we consider the following values (sometimes ranges) for the scenarios.

a) GT alfalfa seed costs

GT alfalfa seeds were sold at US\$6-7.50/lb during its deregulation period, according to various sources (<http://www.purdue.edu/UNS/x/2007a/070323NeesAlfalfa.html>; <http://ipcm.wisc.edu/WCMNews/tabid/53/EntryID/208/Default.aspx>; <http://www.roundupreadyalfalfa.com/home.aspx?page=valuecalculator>)<sup>40</sup>, including its technology fee (trait premium). The technology fee for areas “east of the Rocky Mountains”<sup>41</sup>, ([http://www.farmandranchguide.com/articles/2005/08/31/ag\\_news/regional\\_news/news11.tx](http://www.farmandranchguide.com/articles/2005/08/31/ag_news/regional_news/news11.tx); <http://www.soils.wisc.edu/extension/wfapmc/2006/pap/Undersander2.pdf>) is US\$125 per 50/lb bag, that for those areas west of the Rocky Mountains US\$150 per 50/lb bag.

Seeding rates are those of the conventional alfalfa farming cost studies used as comparison.

b) Glyphosate costs

---

<sup>40</sup>One commenter to APHIS EIS NOI gives the value of US\$6.50 (comment tracking # 803a981a).

Glyphosate prices used in the scenarios area based on those reported by USDA NASS for the same year of the non-GT study being used:

**Table K-9. Glyphosate Prices, 1998-2008, \$ / gallon**

| 1998  | 1999  | 2000  | 2001  | 2002  | 2003  | 2004  | 2005  | 2006  | 2007  | 2008  |
|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| 56.30 | 45.50 | 43.30 | 44.50 | 43.50 | 43.30 | 39.70 | 33.80 | 29.30 | 28.90 | 40.50 |

USDA, NASS, Agricultural Prices, various years.

In 2008, prices of glyphosate seem to have rebounded from a few years of reduced prices.

The number of glyphosate applications used in the scenarios is one or two per year at 22 ounces/acre. One application a year would then require 0.172 gallons and two applications would require 0.344 gallons. These volumes correspond to those used by several of the trials previously reviewed.

c) Weed content

In this exercise, we assume no glyphosate resistance and only glyphosate is used as a herbicide. We leave considerations regarding the potential need for additional herbicides for section 4, where we consider the impact of herbicide resistance to glyphosate. With one or two applications of glyphosate at 22 ounces/acre there is a range of possible results in terms of weed content in the final product, as reviewed above. Improvements in weed content are built into the scenarios as increases in the quality of hay (for example, from good to premium or to supreme) with reflections on prices, according to USDA available alfalfa hay prices for the relevant locality and year. We consider a range of scenarios, from no improvement at all in quality to improvements to supreme alfalfa hay quality.

Table K-10 is intended as an illustrative exercise regarding the possible impact of using GT alfalfa and is not applicable to all situations. It is based on the same circumstances assumed by the UC Cooperative Extension study, while altering seed prices, herbicide use and hay prices.

**Table K-10. Scenarios for GT Alfalfa**

|                                             | Conventional | 1 glyphosate application |          | 2 glyphosate applications |          |
|---------------------------------------------|--------------|--------------------------|----------|---------------------------|----------|
|                                             |              | GT (l)                   | GT (h)   | GT (l)                    | GT (h)   |
| Sales (8 tons/acre)                         | 1480         | 1560                     | 1480     | 1560                      | 1480     |
| Total operating costs/ acre                 | 685.00       | 619.16                   | 620.88   | 624.32                    | 627.76   |
| Return over operating costs                 | 795.00       | 940.84                   | 859.12   | 935.68                    | 852.24   |
| Cash overhead costs                         | 165.00       | 165.00                   | 165.00   | 165.00                    | 165.00   |
| Annual cost recovery: alfalfa establishment | 147.00       | 164.48                   | 177.41   | 165.91                    | 179.32   |
| Annual cost recovery: other                 | 549.00       | 549.00                   | 549.00   | 549.00                    | 549.00   |
| Total costs/acre                            | 1,546.00     | 1,497.64                 | 1,512.29 | 1,504.23                  | 1,521.08 |
| Return over total costs                     | -66.00       | 62.36                    | -32.29   | 55.77                     | -41.08   |

Source: column two from Frate et al., 2008; other columns added.

Columns three and four assume one glyphosate application during the establishment year, columns five and six assume two. Low cost scenarios (l) assume seeds cost US\$6/lb and glyphosate US\$30/ gallon, while the high cost scenarios (h) assume seeds cost US\$7.50/lb and glyphosate US\$40/ gallon. Seed prices already incorporate the technology fee (trait premium) of US\$ 150 per 50 lb bag. Each glyphosate application is assumed to use 22 ounces/acre. The high cost scenario also assumes GT alfalfa generated no benefits in terms of alfalfa quality. The low cost scenario assumes GT alfalfa improved alfalfa quality. Alfalfa that in the UC Cooperative Extension study was assumed to be sold as premium quality will be sold, under the low cost scenario, as supreme quality. Prices are based on those of the USDA AMS, 2007 California Market Summary, where prices for alfalfa hay in the San Joaquin Valley averaged around US\$185/ ton for premium and US\$195/ ton for supreme qualities.

This result depends on the assumptions made regarding the use of herbicides. One way of relaxing these assumptions is by increasing the use of glyphosate applications. Six applications

of glyphosate through the crop year at the high price scenario (or the equivalent addition in cost of other herbicides) would be required for GT alfalfa production costs to surpass those of conventional production, under these specific conditions.

Table K-11 shows the GT alfalfa results suggested by the Wisconsin study reviewed above, as well as extends the exercise to various additional scenarios regarding GT alfalfa. Again, it is intended only as an illustrative exercise regarding the possible impact of using GT alfalfa and is not applicable to all situations. It is based on the same circumstances assumed by Dan Undersander in his study, while altering seed prices, herbicide use and prices, and alfalfa hay prices in the indicated columns. Numbers are rounded to allow for space in table.

**Table K-11. Scenarios for GT Alfalfa**

|                                                  |             |             |             | a           |             | b           |             | C           |             |

Source: first two data columns from Integrated Pest Crop Management, University of Wisconsin; remaining columns elaborated from the base numbers.

\* Original numbers - shown in the first two columns - prorate seed cost over life of stand but leave full technology fee in seeding year. We maintain this assumption, except for in the third column where we prorate the technology fee as well.

a. Two herbicide applications.

b. Two herbicide applications and glyphosate at \$40/ gallon

c. One application, glyphosate at \$40/ gallon and improved hay quality: \$110/ ton, a 10% increase in price. Data from various Midwestern markets<sup>42</sup> suggest \$100/ ton was the price paid for good quality hay within the last year, while premium quality hay would go for 15-35% more, so the quality improvement assumed is quite modest.

In table K-10 we see an improvement in returns over total costs in all scenarios with the use of GT alfalfa. Depending on the specific scenario, the improvement is the result from lower herbicide costs, improved hay quality, or both. In table K-11 Dan Undersander's scenario or reduced GT profit per acre in the seeding year is dependent on not distributing the cost of the technology fee throughout the life of the stand. If this is done, GT alfalfa shows improved profit per acre, suggesting that even in Undersander's scenario, profit per acre would be higher for GT

<sup>42</sup> Pipetone, Minnesota, Hay and Straw Auction; Midwest Hay and Straw Auction, Maurice, Iowa.

alfalfa in years following that of the seeding year. In the remaining scenarios, in two of the three cases, GT alfalfa increased profits in the seeding year, even if the cost of the technology fee were not distributed through the life of the stand.

## 2.3 Summary of Findings

Farming conditions for alfalfa forage vary considerably throughout the United States and we have not identified major cost elements that dominate farming costs under most circumstances. Percentage changes in yields or forage prices have a much greater impact on returns to alfalfa farming for forage than equivalent percent changes in any cost factors. Economies of scale in land preparation mean that technologies (seed varieties) that require more land preparation would be more attractive (and of larger benefit) to larger farms.

GT alfalfa production for forage will have impacts on the cost of seed and the cost of herbicide use. There is also enough evidence to suggest possible benefits on the quality of hay that would presumably lead to higher sales prices. Alfalfa forage farmers aiming at maximizing returns during the time horizon of an alfalfa life stand would likely benefit financially from the adoption of GT alfalfa.

## **3.0 Changes in Alfalfa Seed Farming**

### **3.1 Conventional Alfalfa Seed Farming**

Unlike alfalfa hay production, alfalfa seed production is largely concentrated both geographically and in number of producers. The latest complete information on alfalfa seed production comes from the 2007 Census of Agriculture, when 121,467 acres of alfalfa seed were harvested producing approximately 62 million tons of seeds at an average productivity of approximately 510 lbs/ acre. California was responsible for 31% of this production, Washington 17%, and Idaho 15%, with over 60% of production concentrated in those three states and the remaining also highly concentrated in Western states (Nevada, Oregon, Wyoming, Montana, and Utah). Mueller (Undated a) suggests California's share of production has fallen in recent years and a larger share is coming from the Northwestern states. In 2007, production came from 806 farms. This means that farming conditions for alfalfa seed production are likely more homogeneous than alfalfa hay farming.

However, there still is some variation. Non-dormant varieties of seed tend to be grown in California while dormant varieties are mostly grown in the Pacific Northwest (Mueller, 2005a). Varieties can be proprietary (grown under contract) or public, although almost all varieties today are developed and marketed by private breeding companies (Bouton, 1998). Seeds can also be certified or not.

Alfalfa seed acreage and production increased between 2007 and 2002, reversing the trend of decreases in alfalfa seed production over the last few years. Mueller (2008) attributes reduction in alfalfa seed acreage in California to "changes in economics, environmental constraints, and regulatory issues." Mueller (Undated a) lists among difficulties of alfalfa seed farming in California scarcity of water for crop irrigation and lack of development of new chemicals for insect control due to high registration costs. However, between 2007 and 2002, California gained almost 10,000 acres of alfalfa seed production.

Some farmers grow alfalfa seed as an option to an already existing alfalfa hay stand, allowing the stand to go to seed at the end of the stand life or when there is little water. According to Mueller (2005b) this is the case of most of the seed produced in the Imperial Valley (California), about half of the non-certified seed produced in Utah and much of the dryland seed produced in Montana. This seed would typically not receive certification.

Despite this mixed purpose of many alfalfa fields that generate seeds, there are clear differences in best practices for managing alfalfa for forage and for seed. Dense stands produce higher forage yields but lesser seed yields than thinner stands – as when alfalfa is planted in rows as opposed to solid planting – and certain chemicals used in seed production limit the use of the field for forage (Mueller, 2008). Alfalfa seed farmers also have some costs that are not present in alfalfa hay farming: some insects are only of concern for alfalfa seed production (Mueller, Undated a) and costs with pollination (bees) are considerable since alfalfa is dependent on bees for pollination. Honey bees are cheaper than leafcutter bees or alkali bees but require a long

season for pollination and are therefore only used in California. Leafcutter bees and alkali bees are also more efficient pollinators, although more expensive (Mueller, 2008). Leafcutter bees also have “higher labor requirements, significant annual fluctuations in bee prices, the need for incubation, housing, and net material, as well as a greater sensitivity to pesticides” (Mueller, 2008).

With respect to weeds, the separation of weed seeds from alfalfa seeds after harvesting is costly and control of weeds in the fields is given preference over post-harvest screening and separation (Mueller, Undated b). No primary or secondary noxious weeds are allowed for certified seed and dodder is of particular importance since it may be difficult to control (Mueller, 2008).

Another important difference between alfalfa hay and alfalfa seed production is that the quality of seed (germination, yield, dormancy and other varietal properties) are not readily observable at the moment of purchase and mechanisms come into place to offer clients (and breeding companies) assurance that seeds sold as pertaining to one variety or another will perform as expected. State Crop Improvement Associations – or sometimes Seed Grower Associations – provide certifications that seed production followed minimum standards such as isolation between different alfalfa varieties, absence of prohibited noxious weeds in the field, inspection of conditioning (separation) facilities, maintaining traceability of seed lots and seed testing.

Finally, an important cost in seed production is the seed itself. The development of crop varieties became a predominantly private activity in the past 30 years (Fernandez-Cornejo and Schimmelpenninck, 2004) and the Plant Protection Variety Act of the early 1970s simulated cultivar development in alfalfa (Bouton, 1998). Today almost all new alfalfa cultivars are proprietary.

We have not been able to identify the share of final seed prices represented by such contracts. This is an important aspect to be analyzed and will be dealt with to some extent in future Technical Reports where the possible consequences of supply and demand shifts in the seed market will be discussed. The cost studies reviewed below do seem to address the contracts between seed producers and seed breeding companies.

### *3.1.1 Cost studies*

One 1985 cost study for Fresno, California (Sheesley, 1985) found land rental to be the highest cost component (16.8%) of total annual production cost per acre, followed by irrigation (15.7%), harvesting costs (13.5% - including processing and certification), recovery of capital costs (10.9% - including stand establishment), insect control (9.6%) and pollination (6.7%).

Two cost studies for seed production are available from the University of Nevada Cooperative Extension (Kettle, Myer and Breazeale, 1999a and Kettle, Myer and Breazeale 1999b). Both were done at the end of 1998, one assuming a 250 acre alfalfa seed farm in Pershing County, the other a 750 acre farm in Humboldt County. These studies show pollinators (bees) accounting for roughly 30% of annual production costs and insect control accounting for another 10%, with weed control costs below 10% of the total.

A more recent study is available for Imperial County, California, from the University of California Cooperative Extension (Meister 2004). This study assumes that seeds will be produced for one year from an existing stand of alfalfa hay, noting that “most alfalfa seed is produced from hay fields that will be rotated to another crop in the fall.” Establishment costs are, therefore, absent in the study. Seeds are likely of a non-dormant variety and honey bees are used for pollination. Costs included are considered “typical” for the region, but an excel sheet is provided for farmers to not only fill in with their own costs by complement with additional line items that may have not been included in the study.

Table K-12 below shows the main cost items reported, with the last column showing the percentage total that each line item represents of the total costs.

**Table K-12. Alfalfa Seed Production Costs**

|                              | <b>\$/ acre</b> | <b>% of total costs</b> |
|------------------------------|-----------------|-------------------------|
| Irrigation                   | 35.81           | 7.88%                   |
| Insect Control               | 77.00           | 16.95%                  |
| Pollination                  | 84.00           | 18.49%                  |
| TOTAL GROWING PERIOD COSTS   | 196.81          | 43.32%                  |
| TOTAL HARVEST COSTS          | 108.18          | 23.81%                  |
| Land rent                    | 115.00          | 25.31%                  |
| Cash Overhead                | 34.30           | 7.55%                   |
| TOTAL CASH OVERHEAD COSTS    | 149.30          | 32.86%                  |
| <b>TOTAL CASH COSTS/ACRE</b> | <b>454.29</b>   | <b>100.00%</b>          |

Source: Meister, 2004

Pollination appears as the main operational cost followed by insect control. Overhead cash costs are a third of total and capital recovery costs are not included. Harvest costs are calculated at a 600 lb yield per acre. At a \$1 market value per lb, returns over total cash costs would be \$145.71/ acre. As in the case of alfalfa hay, returns are mostly affected by yield and sales price variations, as shown in table K-13.

**Table K-13. Sensitivity of Returns in Alfalfa Seed Production**

|     | <b>Insect control</b> | <b>Pollination</b> | <b>Irrigation</b> | <b>Yield*price</b> |
|-----|-----------------------|--------------------|-------------------|--------------------|
| 0*  | 145.71                | 145.71             | 145.71            | 145.71             |
| 10% | 138.01                | 137.31             | 142.13            | 205.71             |
| 20% | 130.31                | 128.91             | 138.55            | 265.71             |
| 30% | 122.61                | 120.51             | 134.97            | 325.71             |
| 40% | 114.91                | 112.11             | 131.39            | 385.71             |

Source: elaborated from the data in Meister 2004

\*Initial scenario assumes a yield of 600 lb/ acre at \$1/ lb.

A 2005 cost study is also available from the University of Idaho and the costs reported are considered typical for the southwestern part of the state (Rimbey et al, 2005). The study assumes a farm with 150 acres of alfalfa seed over a three year period (life of stand). Table K-14 summarizes the results. Pollination accounts for 25.1% of the operating costs, followed by insecticides at 16.5%. Irrigation and herbicides are just below 10% of total operating costs each.

**Table K-14. Returns to Alfalfa Seed Production, \$/ acre**

|                                          |               |
|------------------------------------------|---------------|
| Gross returns                            | 875           |
| Pollination                              | 160           |
| Insecticides and application             | 105.65        |
| Herbicides and application               | 59.36         |
| Irrigation                               | 61.08         |
| Operating costs                          | 637.36        |
| Land rent                                | 44            |
| Cash ownership costs (overhead)          | 210.98        |
| Amortized establishment                  | 39.79         |
| Non-cash ownership costs (cost-recovery) | 68.01         |
| Total costs                              | 916.35        |
| <b>Returns over operating costs</b>      | <b>237.64</b> |
| <b>Returns over total costs</b>          | <b>-41.35</b> |

Source: Rimbey et al, 2005

Table K-15 below shows how, again, yield and sales price of seeds have a much greater influence on returns than individual cost components.

**Table K-15. Sensitivity of Returns in Alfalfa Seed Production**

|     | <b>Insect control</b> | <b>Pollination</b> | <b>Irrigation</b> | <b>Weed control</b> | <b>Yield*price</b> |

Source: elaborated from data in Rimbey et al, 2005

### 3.2 GT Alfalfa Seed Farming

The main possible advantage of GT alfalfa for seed production is in weed control. Canevari (2007) notes that the possibility of controlling post emergence dodder before seeding and without injury to alfalfa “would be a significant breakthrough.” However, as noted in the cost studies above, weed control, although fundamental for seed acceptance in the market, is a lesser cost in seed production than other operational costs such as pollination and insect control.

Putnam (2007) notes that the seed industry met in 2007 to discuss more stringent isolation distances for GT alfalfa seed production, given the current concerns with gene flow. Current isolation standards for certified seeds is 165 feet, with tolerance of 10% of the field within the isolation zone (Mueller, 2008). An increase in the isolation distance would have a cost impact on alfalfa seed production, since land rental is often a major cost component.

Our analysis of the impact of GT alfalfa on seed production is limited by lack of more information on breeder company – producer contracts. Benefits or costs to farmers in seed production will likely ultimately be determined by the contracts obtained with breeder companies. These contracts must provide sufficient financial returns to seed farmers so they will engage in the activity. However, bargaining conditions depend on market conditions of

supply and demand and competition between varieties (and breeder companies) may be highly affected by GT deregulation. To the extent possible, we will revisit this issue when we analyze potential supply and demand impacts of GT deregulation in future reports, in case any insights may be drawn from that analysis.

### 3.3 Summary of Findings

Alfalfa seed production is relatively concentrated geographically in the Northwestern part of the country and benefits from specific climatic conditions. Land costs, pollination and insect control tend to be major cost factors with irrigation and herbicide also important depending on location.

The impacts of GT alfalfa adoption for seed production depend on conditions established by the breeder company – producer contracts, that in turn will likely be more or less favorable to producers depending on market (supply and demand) conditions.

## 4.0 Proliferation Over Time of Glyphosate-Resistant Weeds

The analysis done in sections 2 and 3 look at short-term costs and returns of alfalfa farming and are limited to the life of stands. The choice a farmer faces of planting one or another crop must often consider costs and benefits beyond this time horizon. Farmers must, for example, take into consideration the long term value of their lands (soil fertility) as well as how crop rotation choices affect their expected long-term returns and exposure to risk, since some crops may not be substituted by others or even not be planted repeatedly on the same plot (alfalfa is an example due to autotoxicity). It is therefore important to include longer term considerations regarding the potential impact of GT alfalfa on the economics of alfalfa farming.

One long-term consideration is the limitation on crop-rotation. Since GT alfalfa cannot be removed with glyphosate, other methods must be used, whether mechanical, chemical or a combination of these. Orloff and Putnam (1997) suggest plowing is actually the most common method for alfalfa stand removal. However, when herbicides are used for removal, glyphosate seems to be the most commonly used (Canevari 2004). In our Technical Report *Effects of Glyphosate-Tolerant Weeds in Agricultural Systems* (appendix G), we note that potential substitutes for glyphosate in stand removal may limit the following crop of choice. This limitation may have a greater or lesser impact on long term farm profits depending on market circumstances (basically, what would be the crop of choice at a given point in time given expected returns).

Based on the comments to APHIS' Notice of Intent to prepare an Environmental Impact Statement, the long-term issue of greater concern, however, seems to be the impact of a potential increased presence of glyphosate resistant weeds over time, mostly through weed shift. Glyphosate is used to control weeds in GT alfalfa as well as in crops with which alfalfa is rotated (such as GT corn and GT soybeans). If the use of GT alfalfa leads to an increased presence of glyphosate resistant weeds, then glyphosate will have to be substituted or complemented in farming, not only for control of weeds in GT alfalfa fields, but may also for the control of weeds in those crops with which it is rotated.

Based on the cost studies presented in section 2, an increase in the presence of glyphosate resistant weeds in alfalfa fields, requiring the use of other herbicides for control of such weeds, would have the impact of an increase in production costs. In a worst case scenario, GT alfalfa would be treated as in a conventional system and result in alfalfa hay of quality similar to that of a conventional system. The price of the alfalfa seed would then likely also have to be reduced for the survival of the variety in the market.

There is some literature on the costs of herbicide use in GT crops that have been adopted earlier. An increase in herbicide costs over time in these crops would likely reflect cost effects of increased presence of GT resistant weeds. However, we have found no indication of such an increased cost to date. Brooks and Barfoot (2005) report that after 9 years of use of GT soybeans estimates of cost savings actually increased with savings mostly attributed to reduced herbicide costs. They also report continued cost savings with herbicides in the US after eight years of use of herbicide-tolerant cotton (mostly GT) and after six years of use of GT canola.

The continued savings in herbicide costs in GT crops to date does not mean absence of an increase in herbicide resistance, since costs depend not only on the volume of herbicide used but also on prices. It also does not mean increased costs would not still occur in the future. It only means that, to date, we found no evidence of a reversal in the herbicide cost reductions generally identified in GT crops in the United States.

It must also be noted that reduced costs with herbicides do not necessarily mean increased economic returns. Fernandez-Cornejo and McBride (2002) noted that the literature on the economic impact of GT soybeans in the United States is mixed and some farmer surveys show reduced herbicide costs being offset by higher technology fees. The long-term impact of supply and demand and changes in technology fees will impact returns obtained by farmers with GT alfalfa adoption. In future Technical Reports we will revisit this issue to the extent that analysis of supply and demand considerations allow additional inferences to be made.

#### 4.1 Summary of Findings

The increased returns expected for GT alfalfa farming in the short run may or may not continue with time. This depends on market considerations (including technological fees), limitations to crop rotation and cost impacts of any possible increased weed resistance over time. We have found no evidence of increased herbicide costs in GT crops of earlier adoption such as soybeans, cotton, canola and corn.

- Journal of Agronomy

For information on the weed content of alfalfa hay, we took advantage of a search of specialized journals and databases previously done for other Technical Reports<sup>43</sup>.

For data on alfalfa hay prices we used USDA's Agricultural Marketing Service and its Livestock and Grain Hay Reports.

The North American Alfalfa Improvement Conference has a page with links to alfalfa variety test websites in over 20 state: <http://www.naaic.org/Resources/yields.htm>.

---

<sup>43</sup> Search done for Technical Reports: Effects of Glyphosate Tolerant Weeds in Agricultural Systems (Appendix G) and Effects of Glyphosate Tolerant Weeds in non-Agricultural Ecosystems (Appendix H).

## **Appendix K-3.       Likelihood of Benefits of GT Alfalfa Forage by County**

The analysis presented in section 2 suggests GT alfalfa may offer benefits to alfalfa forage farmers in the form of increased quality of forage with decreased herbicide costs. In this appendix we attempt to identify those counties that would most likely benefit from GT alfalfa deregulation, based solely on these cost-return considerations. Any other costs and benefits of GT deregulation are not included in the exercise because they are not part of the scope of this report.

As this Technical Report has not addressed market (demand) restrictions to GT alfalfa (exports, for example), the exercise also abstracts of any demand considerations that may change the potential benefits to farmers of GT alfalfa adoption.

Within these constraints, we offer this exercise as an attempt to rank counties according to the short-term economic benefits accrued to farmers from GT adoption. To the extent possible, we will attempt to refine this analysis when addressing demand (international, GT sensitive, organic) in future Technical Reports.

This exercise assumes the greater the acreage of farms producing alfalfa for forage and the greater the amount of herbicide used on those farms, the more likely farmers of that county will benefit from GT alfalfa deregulation. Herbicide use is seen as an indicator of benefits of GT alfalfa adoption for any of the following reasons: a) greater use of herbicides indicates weeds are a problem in need of management and GT alfalfa weed control is cheaper; or b) greater use of herbicides indicates markets demand cleaner alfalfa and GT alfalfa favors alfalfa hay with a lesser weed content; or c) both. As we cannot claim the same relevance of herbicide use as an indicator of benefit to alfalfa seed farms, this exercise does not include alfalfa seed acreage<sup>44</sup>.

County level data on alfalfa acreage and on herbicide use is available from the 2007 Agricultural Census. The indicator used was built as follows:

1. We identified the share of farming acreage used for alfalfa forage (hay or haylage) in a county: likelihood that a randomly picked acre in the county is planted with alfalfa for forage (a);
2. We identified the share of farming acreage treated with herbicide in a county: likelihood that a randomly picked acre in the county was treated with herbicides in 2007 (b);
3. We excluded those counties with 0 alfalfa forage acreage<sup>45</sup>;
4. We excluded those counties with non-disclosed data for alfalfa hay or herbicide use<sup>46</sup>;

---

<sup>44</sup> Herbicides are more homogeneously used in seed production so this is less of a distinction between alfalfa farms than in forage. Additionally, we were not able to identify as clearly the benefits of GT alfalfa adoption by alfalfa seed farmers.

<sup>45</sup> This was done to differentiate from alfalfa farms with 0 herbicide use in (c)

5. We multiplied (a) and (b), after the exclusions were made: likelihood that a randomly picked acre in the county will both be used for forage alfalfa and treated with herbicides (c);
6. We ranked counties according to (c).

The indicator is highly imperfect and counties highly ranked could presumably reflect herbicide use for other crops co-existing with alfalfa fields with little herbicide use (although, to the extent that weed presence is determined by local environmental conditions, there is likely a correlation between weed issues among crops planted next to each other).

The results are presented in the following pages. Blank cells represent undisclosed data (data withheld to protect identity of individual farms).

Among the top 100 counties, a considerable share is also found in Wisconsin, including the number one ranking county (Brown County, Wisconsin) where alfalfa acreage is high and the use of herbicide may be explained by the importance of dairy farms as consumers of high quality (lesser weed content) alfalfa. The relative scarcity of counties from California among the top ranked counties (with the notable exception of Imperial County) may be explained by the lesser acreage devoted to alfalfa in that state compared to states in the North Central region. If the rankings were done by value of production rather than by acreage, the results would presumably show a greater presence of counties in western states among the top ranked, since yields in that region tend to be higher.

---

<sup>46</sup> We did not do the same for lack of alfalfa haylage data since this would have excluded most counties. For the great majority of counties, alfalfa haylage acreage is a small fraction of hay acreage.
